# Hydrological Summary for the United Kingdom 

## General

With high pressure continuing to dominate synoptic patterns in early April, drought conditions intensified across southern Britain, triggering the introduction of a sprinkler and unattended hosepipe ban by Sutton and East Surrey Water. Despite an unsettled latter half of the month, April rainfall totals were again below average in many of the drought affected catchments. The provisional Nov-Apr rainfall total for E\&W is the $2^{\text {nd }}$ lowest since 1953/54, (1996/97 was similar and 1975/76 was substantially drier) and 6-month rainfall deficiencies are severe across much of the English Lowlands - where, in some areas, the margin between available resources and water demand is particularly narrow. The late April rainfall was very timely, providing a modest boost to reservoir stocks and a late pulse of groundwater recharge in some areas. Stocks in a number of southern reservoirs are appreciably below average (although mostly well above drought minima) but a little above the late spring average for England and Wales as a whole. Groundwater levels are depressed in some responsive southern outcrops but mostly still within the normal range further north. Accelerating evaporation rates are likely to curtail the recharge season very shortly - heralding very low flows, with accompanying environmental stress in spring-fed streams during the coming summer.

## Rainfall

Much of the April rainfall was showery or convective in nature and the varying tracks of the frontal systems which crossed the UK also contributed to substantial spatial variability. There were a few notable storms: Newcastle reported 74 mm in around 48 hrs on the $15 / 16^{\text {th }}$ and rainfall during the $24-27^{\text {th }}$ was especially useful in the South. Nonetheless, April rainfall totals failed to reach the average across most of the English Lowlands with totals $<70 \%$ in parts of London. To the west and north, rainfall totals were generally much healthier with totals exceeding twice the average in parts of the southern Pennines and Scottish Highlands. Broadly, the result of the April rainfall was to reinforce the regional character of the drought, which is focussed on southern and central England. In these regions many catchments have registered six successive months with below average rainfall. Correspondingly, accumulated deficiencies are notably high over wide areas. The Nov-Apr rainfall for E\&W was around $75 \%$ of average but totals fall below $65 \%$ in parts of the South - provisional data suggest that some southern catchments (mostly from Sussex to Dorset) experienced their second driest winter and early spring on record. The preferred tracks of Atlantic frontal systems over this period may be inferred from the exceptionally high 6-month rainfall total registered by the Highland Region in Scotland.

## River Flows

April flow patterns were typical of the spring across most of northern Britain and Northern Ireland, with significant spates in a few catchments - the River Leven (Cleveland) eclipsed its previous maximum April flow on the $16^{\text {th }}$ and in Wales, on the $18^{\text {th }}$, a Flood Warning was issued on the Vyrnwy. By contrast, recessions continued in the English Lowlands with flows in some responsive southern rivers approaching April minima in mid-month. Despite subsequent modest flow recoveries, April runoff totals were $<50 \%$ of average in some rivers (e.g. the Sussex Ouse) and the Piddle (Dorset) reported its $3^{\text {rd }}$ lowest April runoff (after 1976 and 1973) in a 42-yr record. The severity of the
drought is best characterised by runoff totals over the last 6 months. Several rivers draining to the English Channel - including the Exe and Wallington (Hants), both with records of around 50 yrs - reported their second lowest Nov-Apr runoff after the benchmark drought of 1975/76; for the Sussex Ouse the accumulated runoff total was the lowest on record. The virtual absence of any winter recovery in many southern Chalk streams foreshadows notably depressed summer flows. Elsewhere, some substantial Nov-Apr runoff deficiencies were reported (e.g. for the Yscir and Annacloy) but generally the 6 -month totals were in the normal range, and considerably above average in much of Scotland where the Spey registered its $3^{\text {rd }}$ highest total in a $53-\mathrm{yr}$ series.

## Groundwater

Although soil moisture deficits began to build in early April, heavy rainfall during the latter half of the month provided a late pulse of infiltration at a time when groundwater levels (in the lowlands) are normally in recession. Minor groundwater level recoveries or, more likely, inflections in the recessions should be evident on some of the May hydrographs for the index boreholes. The April groundwater levels testify to the drought's severity in the South - at Chilgrove they were the lowest, for the month, since 1976 and rank $8^{\text {th }}$ lowest in a $170-\mathrm{yr}$ record. Depressed levels characterize much of the southern Chalk and the Permo-Triassic sandstones in the South-West. To the north, the drought's impact is less severe. A combination of higher rainfall and, in many cases, longer aquifer response times, has left groundwater levels in most areas within the normal range, albeit below average in many areas - the limestone outcrops particularly. In all but the slowest-responding aquifer units, accelerating evaporation rates during May should ensure that that the seasonal recession in groundwater levels becomes well established - having begun from the lowest spring maximum in at least eight years over wide areas.

The monthly rainfall figures* provided by the Met Office are Crown Copyright and may not be passed on to, or published by, any unauthorised person or organisation. All monthly totals since December 2004 are provisional (see page 12). 1961-2003 regional monthly totals were revised by the Met Office in 2004. The figures for England \& Wales are derived by the Hadley Centre and are updates of the homogenised series developed by the Climate Research Unit; the other national figures are derived from different raingauge networks to those used to derive the CRU data series. Most of the return period estimates are based on tables provided by the Met Office (see Tabony, R. C., 1977, The variability of long duration rainfall over Great Britain, Scientific Paper No. 37) and relate to the specified span of months only (return periods may be up to an order of magnitude less if n-month periods beginning in any month are considered); RP estimates for Northern Ireland are based on the tables for north-west England and those for the Highland region take account of ranking positions. The tables reflect rainfall over the period 1911-70 and assume a stable climate. Artifacts, in the Scottish rainfall series in particular, can exaggerate the relative wetness of the recent past. "See page 12 .

## Rainfall . . . Rainfall . .

May 2004 - April 2005

## Rainfall accumulation maps

The Nov-Apr regional rainfall totals testify to a notable exaggeration in the normal NW-SE rainfall gradient across the UK. Provisional data suggest that, in this timeframe, Southern Region recorded its 2nd lowest rainfall total in at least the last 50 years whilst the Highland Region registered its 3rd highest in a 45 -year series. Rainfall totals over the last 12 months confirm that, over this longer timespan, rainfall deficiencies are again most notable in southern England.

## River flows - April 2005

*Comparisons based on percentage flows alone can be misleading. A given percentage flow can represent extreme drought conditions in permeable catchments where flow patterns are relatively stable but be well within the normal range in impermeable catchments where the natural variation in flows is much greater. Note: the period of record on which these percentages are based varies from station to station. Percentages may be omitted where flows are under review.

## River flow . . . River flow

## River flow hydrographs

The river flow hydrographs show the daily mean flows together with the maximum and minimum daily flows prior to May 2004 (shown by the shaded areas). Daily flows falling outside the maximum/minimum range are indicated where the bold trace enters the shaded areas. The 'national' hydrographs are based on representative networks of gauging stations commanding relatively large catchments.

## Groundwater . . . Groundwater

Groundwater levels normally rise and fall with the seasons, reaching a peak in the spring following replenishment through the winter (when evaporation losses are low and soil moist). They decline through the summer and early autumn. This seasonal variation is much reduced when the aquifer is confined below overlying impermeable strata. The monthly max., min. and mean levels are displayed in a similar style to the river flow hydrographs. Note that most groundwater levels are not measured continuously - the latest recorded levels are listed overleaf.

## Groundwater levels - April 2005

The rankings are based on a comparison between the average level in the featured month (but often only single readings are available) and the average level in each corresponding month on record. They need to be interpreted with caution especially when groundwater levels are changing rapidly or when comparing wells with very different periods of record. Rankings may be omitted where they are considered misleading.
Notes: i. The outcrop areas are coloured according to British Geological Survey conventions.
ii. Yew Tree Farm levels are now received quarterly

Details of the individual reservoirs in each of the groupings listed above are available on request. The featured reservoirs may not be representative of the storage conditions across each region; this can be particularly important during droughts. The storage figures relate to the 1988-2005 period only (except for West of Scotland and Northern Ireland where data commence in the mid-1990's). In some gravity-fed reservoirs (e.g. Clywedog) stocks are kept below capacity during the winter to provide scope for flood attenuation purposes.

# National Hydrological Monitoring Programme 

The National Hydrological Monitoring Programme (NHMP) was instigated in 1988 and is undertaken jointly by the Centre for Ecology and Hydrology Wallingford (formerly the Institute of Hydrology - IH) and the British Geological Survey (BGS). Financial support for the production of the monthly Hydrological Summaries is provided by the Department for Environment, Food and Rural Affairs (Defra), the Environment Agency (EA), the Scottish Environment Protection Agency (SEPA), the Rivers Agency (RA) in Northern Ireland, and the Office of Water Services (OFWAT).

## Data Sources

River flow and groundwater level data are provided by the Environment Agency, the Environment Agency Wales, the Scottish Environment Protection Agency and, for Northern Ireland, the Rivers Agency and the Department of the Environment (NI). In all cases the data are subject to revision following validation (flood and drought data in particular may be subject to significant revision).

Reservoir level information is provided by the Water Service Companies, the EA, Scottish Water and the Northern Ireland Water Service.

The National River Flow Archive (maintained by CEH Wallingford) and the National Groundwater Level Archive (maintained by BGS) provide the historical perspective within which to examine contemporary hydrological conditions.

## Rainfall

Most rainfall data are provided by the Met Office (see opposite). To allow better spatial differentiation the rainfall data for Britain are presented for the regional divisions of the precursor organisations of the EA and SEPA. Following the discontinuation of the Met Office's CARP system in July 1998, the areal rainfall figures have been derived using several procedures, including initial estimates based on MORECS*. Recent figures have been produced by the Met Office, National Climate Information Centre (NCIC), using a technique similar to CARP. A significant number of additional monthly raingauge totals are provided by the EA and SEPA to help derive the contemporary regional rainfalls. Revised monthly national and regional rainfall totals for the post-1960 period (together with revised 1961-90 averages) were made available by the Met Office in 2004; these have been adopted by the NHMP. As with all regional figures based on limited raingauge networks the monthly tables and accumulations (and the return periods associated with
them) should be regarded as a guide only.
*MORECS is the generic name for the Met Office services involving the routine calculation of evaporation and soil moisture throughout Great Britain.

The Met Office
FitzRoy Road
Exeter

The National Hydrological Monitoring Programme depends on the active cooperation of many data suppliers. This cooperation is gratefully acknowledged.

## Subscription

Subscription to the Hydrological Summaries costs $£ 48$ per year. Orders should be addressed to:

Hydrological Summaries
National Water Archive
CEH Wallingford
Maclean Building
Crowmarsh Gifford
Wallingford
Oxfordshire
