# Hydrological Summary for the United Kingdom 

#### Abstract

General November began with mild, boisterous and wet autumnal weather conditions but synoptic patterns produced very much colder weather over the final week. High flows, with modest floodplain inundations, were common during the first fortnight but steep recessions then became established in most rivers. As usual in November, reservoir stocks increased briskly in most western and northern areas and, despite some essential drawdown to moderate the flood risk, overall stocks for England and Wales were appreciably above average in early December. Importantly however, stocks continued to decline in a few South Eastern impoundments (e.g. Bewl) and, reflecting rainfall deficiencies over the post Oct-2004 period, remain seasonally low in the drought affected regions. Groundwater recharge during November was generally healthy in the west and north but the absence of a significant recovery in large parts of the eastern Chalk has resulted in very meagre flows in spring-fed streams, and reinforced the drought's focus on the South East. For much the greater part of the UK the water resources outlook is healthy but in parts of southern and central England the winter and early spring rainfall will need to be appreciably above average to allay concern about water supply and environmental stress in the summer of 2006.

## Rainfall

Synoptic patterns in November were initially cyclonic, bringing substantial rainfall on a westerly/south westerly airflow. Upland western catchments were especially wet - Capel Curig (north Wales) recorded around 200 mm in 7 days - but from around the $11^{\text {th }}$, high pressure predominated until the final week when frontal incursions brought an Arctic airflow across most of the UK. The associated snowfall (reaching Cornwall on the $25^{\text {th }}$ ) caused massive transport disruption - 270 schools were closed in Wales on the $27^{\text {th }}$. However, in a few parts of the English Lowlands precipitation was largely restricted to fog-drip over the latter half of the month. November precipitation totals exhibited large spatial variations, but generally exceeded the average in a broad band from the South West to eastern Scotland where, locally, totals exceeded twice the monthly average (e.g. in parts of the Grampians). By contrast, Northern Ireland and south western Scotland were relatively dry and, of greater water resources significance, below average totals characterised much of the English Lowlands; parts of Kent registered $<40 \%$. Autumn (Sep-Nov) rainfall totals were moderately above average in most regions but, unhelpfully in relation to the drought, the driest areas (reporting $<80 \%$ ) were in the South East. Here, a number of catchments have registered only one or two months with above average rainfall since October 2004. In this 13 -month timespan, the E\&W rainfall total is the $3^{\text {rd }}$ driest since 1975/76 (1988/89 and 1995/96 were drier). More significantly, large parts of the South-East registered their $2^{\text {nd }}$ lowest total (after 1988/ 89) since $1933 / 34$; with the greater part of the overall deficiency built up during the winter months the impact on runoff and aquifer recharge has been substantial.

## River Flows

November flows exhibited a very wide range especially in responsive catchments. The late October recovery in runoff continued; spate conditions and Flood Warnings were common during the first 10 days - culminating on the $9^{\text {th }}$ when the Rivers Gwilli and Dewi Fawr (in South Wales) both registered their highest levels on record. Flooding was locally severe (e.g. in Haverfordwest) and the saturated soils triggered a number of landslides (e.g. near Bethesda and Ebbw Vale). On the Severn,
demountable flood barriers were employed at Bewdley and Worcester. More generally, storm debris and leaffall contributed to local drainage problems. From midmonth, recessions were steep - aided by frozen upland catchments - and, by month end, flows were approaching early winter minima (e.g. in the Forth) in many responsive catchments. After many months ( 31 for the Lambourn) of below average flows, runoff rates in many spring-fed streams were also depressed. Such impermeable catchments aside, November runoff totals were mostly within the normal range. A more revealing picture of the drought's persistence and severity is provided by the runoff accumulations since October 2004. Deficiencies of well over $30 \%$ characterise many southern and central catchments, and are unprecedented for a few rivers in the South-East (e.g. the Medway and Sussex Ouse).

## Groundwater

With November rainfall favouring the west and north, where soils were close to saturation, substantial infiltration produced strong groundwater level recoveries in most sandstone and limestone aquifers (levels increased by $>20 \mathrm{~m}$ at Alstonfield). Very helpful recoveries were also registered in much of the western Chalk (e.g. at Ashton Farm and West Woodyates). But no seasonal upturn was evident during November in much of the central and eastern Chalk outcrops - or for some Permo-Triassic sandstones aquifer units - where soil moisture deficits mostly remained above average in late November. Although November groundwater levels at most index wells were in the normal range, continuing recessions have left notably low levels in the Permo-Triassic sandstones of the Midlands and in parts of the central and eastern Chalk. At the Redlands, Stonor and Little Bucket index wells November levels were seasonally depressed, and close to drought minima. For the Chalk as a whole there has been a modest increase in groundwater resources since October when overall resources were estimated at their lowest since the autumn of 1997. In order for groundwater to exercise a strong moderating influence on any potential summer drought (in the English Lowlands) in 2006, above average rainfall will be needed over Dec-April period to help ensure that the 2006 recessions begins from nearaverage spring peaks.

## Rainfall accumulation maps

The Sept-Nov rainfall for the UK added to a cluster of recent wet autumns; eight of the last nine have registered above average rainfall. North-eastern England was especially wet, recording its highest autumn rainfall since 1984. Reflecting the preferred tracks of most Atlantic low pressure systems since the autumn of 2004, accumulated rainfall totals for northern Scotland are also notably wet (the Nov-2004 to Nov-2005 total vying with 1991/92 as the wettest in a series from 1914). The relative paucity of frontal rainfall over the 13 -month period is very evident across southern England where deficiencies similar to that of Southern Region would be expected, on average, only once every 30-40 years.

## River flow . . . River flow

## River flows

*Comparisons based on percentage flows alone can be misleading. A given percentage flow can represent extreme drought conditions in permeable catchments where flow patterns are relatively stable but be well within the normal range in impermeable catchments where the natural variation in flows is much greater. Note: the period of record on which these percentages are based varies from station to station. Percentages may be omitted where flows are under review.

## River flow . . . River flow

## River flow hydrographs

The river flow hydrographs show the daily mean flows together with the maximum and minimum daily flows prior to December 2004 (shown by the shaded areas). Daily flows falling outside the maximum/minimum range are indicated where the bold trace enters the shaded areas.

## Groundwater . . . Groundwater

Groundwater levels normally rise and fall with the seasons, reaching a peak in the spring following replenishment through the winter (when evaporation losses are low and soil moist). They decline through the summer and early autumn. This seasonal variation is much reduced when the aquifer is confined below overlying impermeable strata. The monthly max., min. and mean levels are displayed in a similar style to the river flow hydrographs. Note that most groundwater levels are not measured continuously - the latest recorded levels are listed overleaf.

## Groundwater . . Groundwater

## Groundwater levels - November 2005

The rankings are based on a comparison between the average level in the featured month (but often only single readings are available) and the average level in each corresponding month on record. They need to be interpreted with caution especially when groundwater levels are changing rapidly or when comparing wells with very different periods of record. Rankings may be omitted where they are considered misleading.
Notes: i. The outcrop areas are coloured according to British Geological Survey conventions.
ii. Yew Tree Farm levels are now received quarterly.

# National Hydrological Monitoring Programme 

The National Hydrological Monitoring Programme (NHMP) was instigated in 1988 and is undertaken jointly by the Centre for Ecology and Hydrology Wallingford (formerly the Institute of Hydrology - IH) and the British Geological Survey (BGS). Financial support for the production of the monthly Hydrological Summaries is provided by the Department for Environment, Food and Rural Affairs (Defra), the Environment Agency (EA), the Scottish Environment Protection Agency (SEPA), the Rivers Agency (RA) in Northern Ireland, and the Office of Water Services (OFWAT).

## Data Sources

River flow and groundwater level data are provided by the Environment Agency, the Environment Agency Wales, the Scottish Environment Protection Agency and, for Northern Ireland, the Rivers Agency and the Department of the Environment (NI). In all cases the data are subject to revision following validation (flood and drought data in particular may be subject to significant revision).

Reservoir level information is provided by the Water Service Companies, the EA, Scottish Water and the Northern Ireland Water Service.

The National River Flow Archive (maintained by CEH Wallingford) and the National Groundwater Level Archive (maintained by BGS) provide the historical perspective within which to examine contemporary hydrological conditions.

## Rainfall

Most rainfall data are provided by the Met Office (see opposite). To allow better spatial differentiation the rainfall data for Britain are presented for the regional divisions of the precursor organisations of the EA and SEPA. Following the discontinuation of the Met Office's CARP system in July 1998, the areal rainfall figures have been derived using several procedures, including initial estimates based on MORECS*. Recent figures have been produced by the Met Office, National Climate Information Centre (NCIC), using a technique similar to CARP. A significant number of additional monthly raingauge totals are provided by the EA and SEPA to help derive the contemporary regional rainfalls. Revised monthly national and regional rainfall totals for the post-1960 period (together with revised 1961-90 averages) were made available by the Met Office in 2004; these have been adopted by the NHMP. As with all regional figures based on limited raingauge networks the monthly tables and accumulations (and the return periods associated with them) should be regarded as a guide only.
*MORECS is the generic name for the Met Office services involving the routine calculation of evaporation and soil moisture throughout Great Britain.

[^0]:    Details of the individual reservoirs in each of the groupings listed above are available on request. The featured reservoirs may not be representative of the storage conditions across each region; this can be particularly important during droughts. The storage figures relate to the 1988-2005 period only (except for West of Scotland and Northern Ireland where data commence in the mid-1990's). In some gravity-fed reservoirs (e.g. Clywedog) stocks are kept below capacity during the winter to provide scope for flood attenuation purposes.
