# Hydrological Summary for the United Kingdom 

## General

April rainfall commonly has a disproportionate influence on the resources outlook for the ensuing summer. It was certainly influential this year when, following a dry early spring, April was very unsettled across much the greater part of the UK with most areas reporting well above average rainfall; intense downpours triggered localised, mostly urban, flooding. With soils still generally moist, the hydrologically effective rainfall provided a welcome boost to reservoir stocks. Contents fell in a few reservoirs (e.g. in the South-West and Northern Ireland) but overall stocks for England and Wales increased modestly to stand appreciably above average in early May, and considerably above corresponding stocks in 2003. Generally, the April rainfall patterns favoured the major aquifer outcrop areas and the seasonally late infiltration was sufficient to moderate or reverse the early spring recessions. At month-end, groundwater resources were close to average in almost all areas. Substantial long term rainfall deficiencies remain but the water resources outlook for the summer is generally good.

## Rainfall

Low pressure dominated synoptic patterns for much of last month and the proverbial April showers were decidely more vigorous than usual; widespread frontal rainfall also contributed to a provisional UK total for April which ranks amongst the wettest half dozen since 1966 . The 18 th was especially wet with much of eastern England and the Borders registering rainfall totals $>20 \mathrm{~mm}$. Intense localised downpours were especially common over the final week. Following a short heat-wave, thunderstorms on the 26th and 27th resulted in some exceptional storm totals e.g. 43 mm in 2 hrs at Bromsgrove (26th); 33 mm in an hour near Sheffield (27th). Further vigorous thunderstorms affected much of southern England as warm, moist air pushed up from France on the 27th. The showery nature of much of the April rainfall made for substantial local variability in the monthly totals but only a few areas - mostly in Wales and north-west England - reported below 75\% of average; Anglesey was especially dry. By contrast, much of the Scottish Highlands registered around twice the average, with similar percentages characterising parts of the Midlands and the North-East. Regional rainfall deficiencies since January 2003 remain very substantial but the above average rainfall over the last 6 months has largely banished the spectre of drought.

## River Flows

River flows in most catchments were seasonally depressed and in brisk recession entering April, but - counter to the normal seasonal trend - they increased over the month and in a few areas modest floodplain inundations occurred during the latter half of April. Heavy runoff from the North York Moors on the 18/19th provoked flood warnings on the Derwent and localised flooding was common on the 26th/27th (e.g in Worcester, Sheffield and London) as local drainage systems were overwhelmed. Flow patterns in the Thames typified many rivers with runoff rates increasing from considerably below to appreciably above through April. Correspondingly, April runoff totals were mostly well within the normal range but with significant variations reflecting both regional rainfall patterns and catchment geology. In Devon, the Taw recorded only around $40 \%$ of its April average whereas, in the North-

East, the Leven reported $>200 \%$. Local contrasts where particularly evident in the English Lowlands where rivers draining impermeable catchments responded much more quickly to the April rainfall than spring-fed streams and rivers. Runoff over last six months (Nov-April) is appreciably below average across almost all of the UK and longer term accumulations - reflecting the impact of the 2003 drought - are depressed over wide areas. Many rivers (including the Trent, Exe and Medway) have registered only a single month with flows above the average since Jan 2003; in this timeframe the 15-month accumulations for the Exe and Medway rank as the 2nd and 3rd lowest, respectively, in records of almost 50 years. The late-spring return to more typical flow rates has therefore been particularly welcome.

## Groundwater

April began with soil moisture deficits building across many eastern aquifer outcrop areas and, with evaporation losses accelerating, the prospect for further significant recharge was poor. In the event, the April rainfall was generally well distributed through the month and $30 \%$, or more, above average across most major aquifer units; in the east, the frontal rainfall on the 18th was especially beneficial. This was sufficient to re-initiate infiltration and provide a seasonally late pulse of recharge. Though modest in magnitude, this generated an upturn in groundwater levels (e.g. at Ampney Crucis in the Jurassic Limestone and Rockley in the Chalk). April groundwater levels in the Chalk reflected the responsiveness of the aquifer to recharge and late-spring groundwater levels are now well within the normal range for almost all index sites. Despite steep declines in Feb/March, a similar pattern can be recognised in the other limestone aquifers. Spatial variation is much more evident in the Permo-Triassic sandstones where notably high levels at Yew Tree Farm contrast with relatively depressed water-table in southern Scotland, however, most PTs index sites registered typical spring levels. Overall groundwater resources were only a little below average at month-end with, in some areas, the likelihood of further modest recoveries before the summer recessions become firmly established.

## Rainfall . . . Rainfall . .

## Key

Abercental Normal range

November 2003 - April 2004
February 2003 - April 2004

## Rainfall accumulation maps

A comprehensively wet April, except for the western fringes of EW and parts of the North West, has improved the GB water resources situation. Long term deficiencies are still significant, however, and the 15 month deficiencies, in both the Tay and Forth regions caused them to be ranked the 5th driest Feb-Apr in 44 years. By contrast, the 6 month Nov-April rainfall accumulations exceeded $20 \%$ of average in parts of the SE (notably in the Thames region) ensuring a resource situation within the normal range.

## River flows - April 2004

*Comparisons based on percentage flows alone can be misleading. A given percentage flow can represent extreme drought conditions in permeable catchments where flow patterns are relatively stable but be well within the normal range in impermeable catchments where the natural variation in flows is much greater. Note: the period of record on which these percentages are based varies from station to station. Percentages may be omitted where flows are under review.

## River flow . . . River flow

## Monthly river flow hydrographs

The river flow hydrographs show the monthly mean flow (bold trace), the long term average monthly flow (dotted trace) and the maximum and minimum flow prior to 2001 (shown by the shaded areas). Monthly flows falling outside the maximum/ minimum range are indicated where the bold trace enters the shaded areas.

## River flow . . . River flow

Notable runoff accumulations (a) November 2003 - April 2004, (b) February 2003 - Aprl 2004

## Groundwater . . . Groundwater

Groundwater levels normally rise and fall with the seasons, reaching a peak in the spring following replenishment through the winter (when evaporation losses are low and soil moist). They decline through the summer and early autumn. This seasonal variation is much reduced when the aquifer is confined below overlying impermeable strata. The monthly max., min. and mean levels are displayed in a similar style to the river flow hydrographs. Note that most groundwater levels are not measured continuously - the latest recorded levels are listed overleaf.

## Groundwater. . . Groundwater

## Groundwater levels - April 2004

The rankings are based on a comparison between the average level in the featured month (but often only single readings are available) and the average level in each corresponding month on record. They need to be interpreted with caution especially when groundwater levels are changing rapidly or when comparing wells with very different periods of record. Rankings may be omitted where they are considered misleading.
Notes: i. The outcrop areas are coloured according to British Geological Survey conventions.
ii. The Newbridge borehole supercedes Redbank (which was affected by groundwater abstraction). Yew Tree Farm levels are now received quarterly.

## Reservoirs . . . Reservoirs

## Guide to the variation in overall reservoir stocks for England and Wales

Comparison between overall reservoir stocks for England and Wales in recent years

| () figures in parentheses relate to gross storage - denotes reservoir groups |  |  |  | +excludes Lough Neagh |  |  |  | *last occurrence - see footnote |  |  |

Details of the individual reservoirs in each of the groupings listed above are available on request. The featured reservoirs may not be representative of the storage conditions across each region; this can be particularly important during droughts. The storage figures relate to the 1988-2004 period only (except for West of Scotland and Northern Ireland where data commence in the mid-1990's). In some gravity-fed reservoirs (e.g. Clywedog) stocks are kept below capacity during the winter to provide scope for flood attenuation purposes.

## Location map . . . Location map

# National Hydrological Monitoring Programme 

The National Hydrological Monitoring Programme was instigated in 1988 and is undertaken jointly by the Centre for Ecology and Hydrology Wallingford (formerly the Institute of Hydrology - IH) and the British Geological Survey (BGS). Financial support for the production of the monthly Hydrological Summaries is provided by the Department for Environment, Food and Rural Affairs (Defra), the Environment Agency (EA), the Scottish Environment Protection Agency (SEPA), the Rivers Agency (RA) in Northern Ireland, and the Office of Water Services (OFWAT).

## Data Sources

River flow and groundwater level data are provided by the Environment Agency, the Environment Agency Wales, the Scottish Environment Protection Agency and, for Northern Ireland, the Rivers Agency and the Department of the Environment (NI). In all cases the data are subject to revision following validation (flood and drought data in particular may be subject to significant revision).

Reservoir level information is provided by the Water Service Companies, the EA, Scottish Water and the Northern Ireland Water Service.

The National River Flow Archive (maintained by CEH Wallingford) and the National Groundwater Level Archive (maintained by BGS) provide the historical perspective within which to examine contemporary hydrological conditions.

## Rainfall

Most rainfall data are provided by The Met Office (see opposite). To allow better spatial differentiation the rainfall data for Britain are presented for the regional divisions of the precursor organisations of the EA and SEPA. Following the discontinuation of The Met Office's CARP system in July 1998, the areal rainfall figures have been derived using several procedures, including initial estimates based on MORECS*. Recent figures have been produced by The Met Office, National Climate Information Centre (NCIC), using a technique similar to CARP. An initiative is underway with The Met Office to provide more accurate areal figures and, since October 1999, to include more raingauges in the analysis. A significant number of additional monthly rainfall totals are currently being provided by the Environment Agencies. As with all regional figures based on limited raingauge networks the monthly tables and accumulations (and the return periods associated with them) should be regarded as a guide only.
*MORECS is the generic name for The Met Office services involving the routine calculation of evaporation and soil moisture throughout Great Britain.

[^0]:    The monthly rainfall figures* are copyright of The Met Office and may not be passed on to, or published by, any unauthorised person or organisation. All monthly totals since November 2003 are provisional (see page 12). The figures for England \& Wales are derived by the Hadley Centre and are updates of the homogenised series developed by the Climate Research Unit; the other national figures are derived from different raingauge networks to those used to derive the CRU data series. The return period estimates are based on tables provided by The Met Office (see Tabony, R. C., 1977, The variability of long duration rainfall over Great Britain, Scientific Paper No. 37) and relate to the specified span of months only (return periods may be up to an order of magnitude less if $n$-month periods beginning in any month are considered); RP estimates for Northern Ireland are based on the tables for north-west England. The tables reflect rainfall over the period 191170 and assume a stable climate. Artifacts, in the Scottish rainfall series in particular, can exaggerate the relative wetness of the recent past. *See page 12.
