

WMO Publication 47: Consistency Checking and Gap Filling, Version 1.0

David I. Berry and E. C. Kent

July-06

1 Introduction

WMO Publication 47 (Pub. 47) contains information on the Voluntary Observing Ship (VOS) observations contained within ICOADS. However, this data has been collected over a 50 year period by numerous countries and in a number of different formats, ranging from 13 fields in the 1950's up to around 120 fields in the modern editions. The changing formats and contents of Pub. 47 are described in Kent *et al.* (2006). The addition of new fields leads to information becoming available which may be valid for records in earlier editions. As a result, it should be possible to increase the amount of information available from Pub. 47 by copying new fields into earlier additions as they become available.

Due to the operational nature of Pub. 47 and its collection by different agencies there are a large number of coding differences and typographical errors in the metadata. Also, due to WMO regulations, once data has been added to Pub. 47 by a country that data persists until the next entry from that country. This leads to out of date metadata and may lead to ambiguous entries where multiple records for the same ship from different countries exist in the same edition.

This report describes the process used to homogenize the metadata data set, correct typographic and coding errors and to copy information into the earlier editions when new fields are added. Section 2 describes the process of homogenizing the dataset and section 3 makes an assessment of the homogenization.

2 Method

The following sections describe the process undertaken to clean the metadata, merge duplicate entries and correct coding or typographical errors. The process can be broken down into 5 steps:

- 1) Generate list of unique entries and mapping tables for each field
- 2) Perform code mapping and subset Pub. 47 editions by country
- 3) Compare editions by country and generate list of updates

- 4) Read in updates from list generated in (4) and generate master table
- 5) Set validity dates in master table

2.1 Code Mapping

Due to the long time scales over which Pub. 47 has been collected, the operational capacity in which it's collected and the numerous centres used for collection, many coding differences and typographical errors exist. If left uncorrected, these will lead to false negatives in the record matching process (Section 2.3). Hence, to minimize these differences a list of unique entries for the different fields have been generated based on the data available for the period 1973 – 2006. Code mapping tables have then been generated from these lists and used to correct typographical errors and ensure consistent coding of the different elements. Tables 1a – 1p give the code mapping tables used. Column 1 gives the original code, column 2 the new code and column 3 a description of the code.

2.2 Contribution by country

Due to WMO regulations, once a set of entries from a country are submitted to Pub. 47 those details persist until the next set of entries from that country. Hence, if no update is made by that country the records will persist, leading to metadata which may be many years out of date. Additionally, this may lead to multiple entries for a call sign if a different country then recruits a ship by that call sign.

To minimise the impact of data persisting in Pub. 47 a list of updates by each country has been generated. The list has been generated by sub-setting each Pub. 47 edition by country, creating a new set of files each containing only the metadata for an individual country and edition. For each country, these are then compared to each other and where the files are the same the file from the earlier edition is kept. The file from the later edition is deleted. The files kept are assumed to be the updates supplied by the various countries to the WMO for inclusion in Pub. 47. Table 2 gives a list of the updates by individual countries. Column 1 gives the different recruiting countries, column 2 the list of updates by those countries and column 3 any notes about that edition.

At this stage the metadata records are assigned a validity period of one issue, i.e. one year between 1955 and 1998 and 3 months from 1998 onwards, beginning on the first day of that issue. These validity dates are then reset at a later stage to extend 1 year before the

records first appears and for 5 years after the record is last updated (see Section 2.4)

2.3 Record Matching

To minimise the number of entries in the processed metadata but maximise the amount of information available a master table of metadata records has been created. The flowchart below shows the process used to create the master table from the records in the list of updates, with the process being repeated for each record.

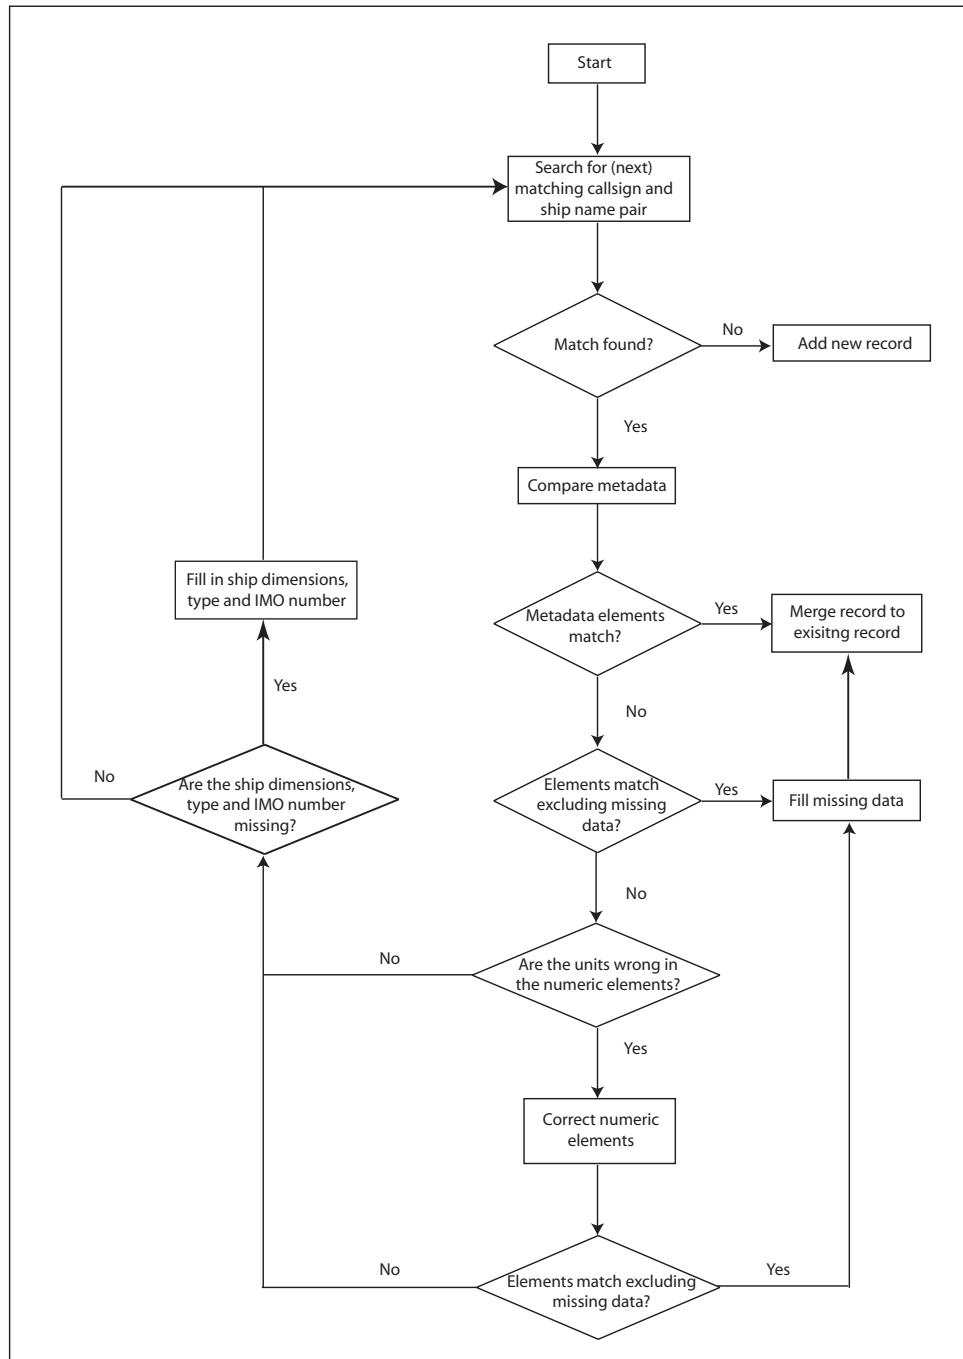

Figure 1. Flowchart of process to create master metadata table

When an entry is entered into the master table it is compared against the other records already in the table. If the call sign and soundex¹ of the ship name for the record being entered match an entry already in the master table the major metadata elements are compared. Soundexes of the ship names are used to avoid false negatives due to typographical errors and spelling differences in the names and to maximise the number of matches. A number of the major elements have multiple sections or sub-elements. These are listed together with the major metadata elements in Table 3.

For metadata elements which include a number of sub-elements the sub elements must all match to be classed as a match. If the sub-elements have data in one record but this information is missing in the other than it is classed as a partial match. A number of the elements can also have multiple values as well as sub-elements. The order in which the instruments are recorded is not specified in Pub. 47 with the exception of the metadata on SST measurement method and depth. Hence, where multiple values exist for a metadata element then all possible combinations are checked for a match. If both metadata records have one instrument set and the other set to missing the set instruments must match for it to be classed as a match or partial match. For SST the order recorded is specified, hence there must a direct match or partial match between the SST instruments for the records to be classed as matching or partially matching. For example, SST method and depth 1 in the record being added must match SST method and depth 1 in the record compared against for the records to be classed as matching.

From the matching process a number of different outcomes are possible

- 1) Identical metadata
- 2) Matching metadata but with missing elements
- 3) Matching metadata but with differences in the numeric elements
- 4) Different metadata

The following sections describe the processes for the above outcomes

¹ A soundex algorithm phonetically encodes a word, with phonetically similar words having identical encoding.

2.3.1 Identical Metadata

For two metadata records to be classed as an identical match all elements and sub elements must have corresponding entries in both records. If an identical match is found the two records are merged and the validity dates set to the earliest valid from date and the latest valid to date. For example, for two records valid from 1st January 1993 to 31st December 1993 and 1st January 1994 to 31st December 1994 the validity period would be set to 1st January 1993 – 31st December 1994.

2.3.2 Partial match - matching metadata but with missing elements

For two records to be classed as partially matching the metadata elements and sub elements present in both files must either have a corresponding entry in each file or be matched to missing data. For records classed as a partial match the records are merged, with the missing elements and sub elements filled from the more complete record and the validity dates set to cover both records, as for identical metadata.

2.3.3 Matching metadata but with differences in the numeric elements

Due to the operational nature of Pub. 47 and the long time scales over which it has been collected a number of the records have been entered in units other than metres or used the height above deck as the reference point for the instrument heights rather than height above max load line. Hence for records where the metadata elements match or form a partial match but the numeric elements are different a number of unit conversions are tried. For two similar records but with different numeric elements conversions from decimetres, centimetres, and millimetres are tried with the larger value converted. If all the values tested are within 0.5 m the conversion is assumed to be correct. If the conversion is not within 0.5 m the original height and depth elements are adjusted by the freeboard. If after adjustment the heights are within 0.5m the adjustment is assumed to be correct.

2.3.4 Different metadata

If the metadata records are different but the call signs and soundexes of the ship names match then both records are checked to see if any of the ship dimensions, type or IMO number are missing. If any of these elements are missing in either the record being added or the record already in the master table but present in the other record then the missing elements

are filled. If the metadata in the records do not match the master table is searched for the next record sharing the call sign / ship name pair. If no other records are found a new record is inserted into the table.

2.4 Setting of validity dates

Once all the records in the updates have been added to the master table the validity dates for the records are extended. To maximise the number of matches with the observations from the VOS the validity dates for the records are extended to be valid for one year before the record first appears and for five years after the last update for that record. If there is any overlap in the validity dates for a call sign then the validity end date of the earlier record is used to set the start date for the validity period of the later one.

3 Results

If the metadata has been improved by the homogenization and cleaning we should see a reduction in the number of metadata records, an increase in the information available from the metadata database and an increase in the number of observations from ICOADS which we can match to the metadata. We should also see a decrease in the number of invalid entries for the different fields.

3.1 Reduction in number of records

Before the cleaning and homogenization Pub. 47 contains around 470 000 different records in 94 different files and 7 different formats. After processing the data are contained in one file with a common format and approximately 90 000 records.

3.2 Completeness of records

As a measure of the completeness of the metadata records a number of the major fields of interest are selected (Table 4). For each record these fields are checked and the fraction complete calculated as the number of fields with data divided by the number of fields checked. The completeness of each record is then averaged over each year between 1954 and 1998 and each quarter from 1998 onwards. Figure 2 shows a time series of the completeness for both the original data and the filled dataset. Only metadata records with observations in ICOADS have been used. Similar results are found using all data.

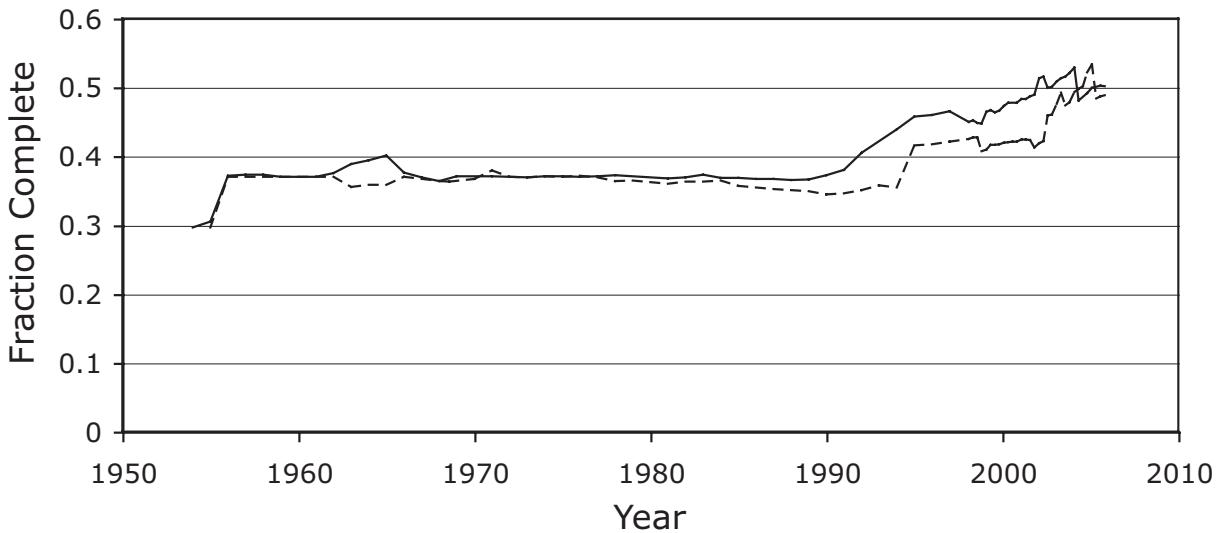

Figure 2. Fractional completeness of Pub. 47 records averaged over editions for the filled (solid line) and original data (dashed line)

Over the early part of the record there is little extra information added through the merging and filling process. This is due to no new fields and little extra information becoming available until the early 1990's. The addition of a number of new fields in 1995 can be seen in the original data. The impact of these new fields can also be seen in the filled dataset, with an increase in the completeness of the records from 1980 onwards due to this information being copied into the earlier records. A similar change is seen around 2002 when additional fields are added. At the end of the record there is a drop in the completeness due to a large number of new records being added to Pub. 47 containing little information other than ship name, type and recruiting country. This drop in completeness appears in the filled dataset first due to the extension of the validity dates.

3.3 Match to Observations

As a result of the extension of the validity dates we should see a greater number of matches to observations from VOS contained in ICOADS. This increase can be seen in Figures 3 and 4. Figure 3 shows the number of unique call signs in ICOADS (blue), the number which can be matched to metadata in the filled dataset (red) and the number matched to metadata in the original files (green). Figure 4 shows the number of VOS observations from ICOADS (blue), the number matched to metadata from the filled dataset (red) and the number matched to the original data (green).

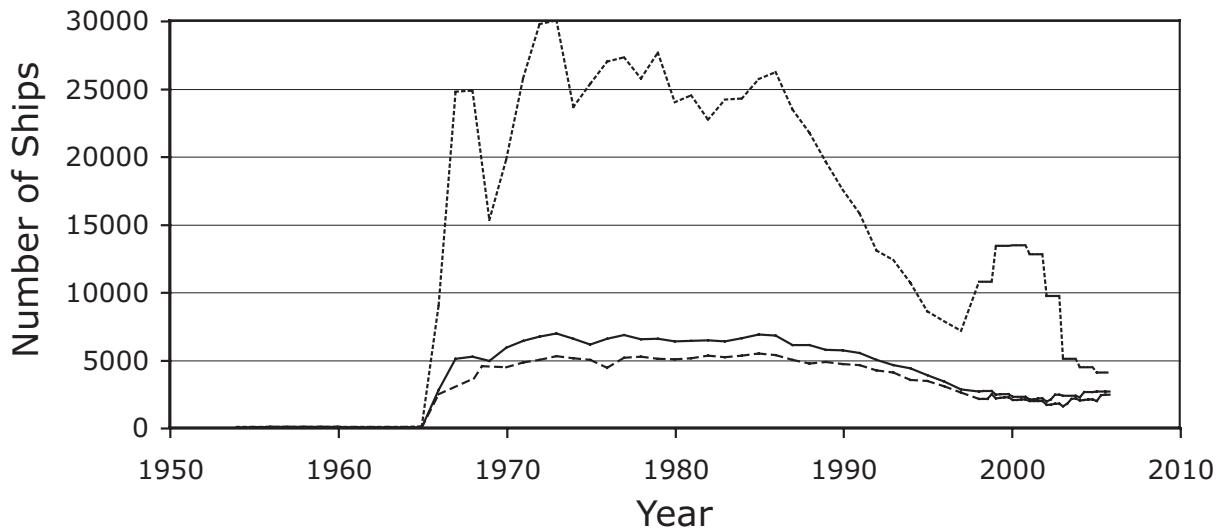

Figure 3. Number of unique call signs in ICOADS (dotted line), the number which can be matched to metadata in the filled dataset (solid line) and the number matched to metadata in the original files (dashed line)

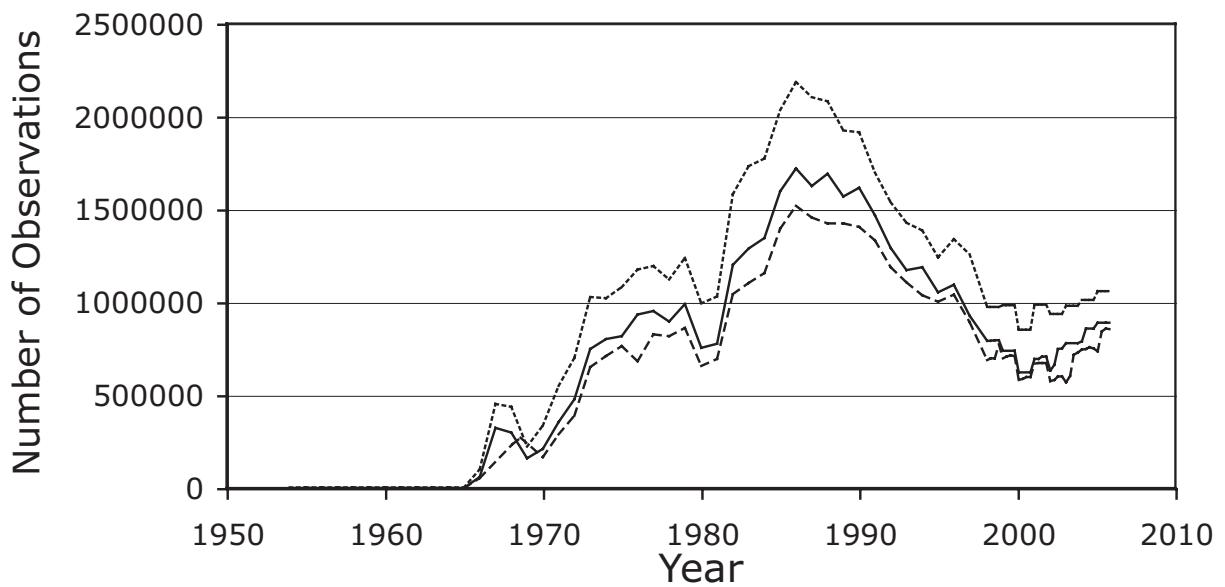

Figure 4. Number of VOS observations from ICOADS (dotted line), the number matched to metadata from the filled dataset (solid line) and the number matched to the original data (dashed line)

Using the filled dataset we are matching approximately 20% more call signs from ICOADS to metadata compared to the original Pub. 47 dataset. However, there are a large number of call signs unmatched from ICOADS. Whilst there are a large number of unmatched call signs Figure 4 shows we do match a large proportion of the observations to

metadata, with around 70 – 80 % of observations matched to metadata. This suggests there may be a small number of observations in ICOADS with corrupted or masked call signs. We see approximately 10 % more matches between observations and metadata using the filled metadata compared to the original Pub. 47.

4 Summary and Future Work

Overall there has been an improvement in the metadata database, with a large reduction in the number of entries, an increase in the amount of information available and an increase in the number of observation in ICOADS matched to metadata. Figure 5 shows the fractional completeness of Pub. 47 from the filled (blue) and original (red) data scaled by the percentage of the observations from ICOADS matched to metadata. Over the majority of the period we see an increase of 20 – 25 % in the amount of information available from the filled dataset compared to the original metadata. This is both from backfilling of metadata as new fields become available and from extending the validity periods of the individual records.

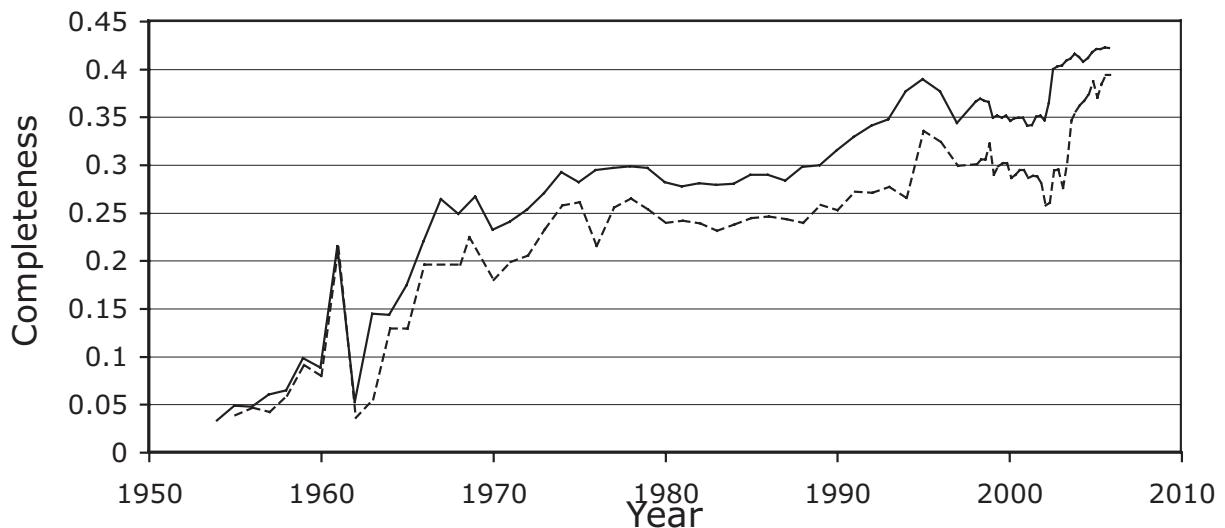

Figure 5. Completeness Index for Pub. 47 / ICOADS based on the filled dataset (solid line) and the original Pub. 47 (dashed line)

Whilst the metadata has been improved and the amount of available information increased by the processes described in this report further improvements are still possible.

- Recovery of instrument heights with ambiguous units
- Spurious changes to measurement methods
- Improved duplicate handling
- Addition of newly digitized metadata

A number of heights have been discarded due to ambiguous units of measurement and it should be possible to manually recover these values.

A number of countries change measurement methods for several editions and then change back to the original values. These changes are thought to be spurious and can also be corrected.

A number of early Pub. 47 editions and other metadata have recently become available, either in digital format or the data are in the process of being digitized. This data will be added to the database as it becomes available.

Table 2. List of updates by Country

Major element	Sub-element	Notes
Ship details	Call sign	
	Ship name	
	Vessel Type	
	Length of vessel	
	Breadth of vessel	
	Draft of vessel	
	Freeboard of vessel	
	Cargo height	
	Distance from bridge to bow	
	IMO Number	
Recruiting Country		
Change Date		
Baseline Check		
Automation		
Barometer 1	Barometer Model / Manufacturer / Serial Number	
	Calibration Date	
	Units	
	Type	
	Location	
	Height	
Barometer 2	Barometer Model / Manufacturer / Serial Number	
	Calibration Date	
	Units	
	Type	
	Location	
	Height	
Barograph 1		
Barograph 2		
Thermometer 1	Thermometer Model / Manufacturer / Serial Number	
	Type	
	Exposure	
	Location	
	Scale	
	Height	
Thermometer 2	Thermometer Model / Manufacturer / Serial Number	
	Type	
	Exposure	
	Location	
	Scale	
	Height	
Platform Height		Replaced by barometer and thermometer heights after 19xx
Hygrometer 1	Type	
	Exposure	
Hygrometer 2	Type	

Major element	Sub-element	Notes
SST 1	Exposure	
	Type	
	Depth	
SST 2	Type	
	Depth	
	Type	
Anemometer 1	Depth	
	Anemometer Model / Manufacturer / Serial Number	
	Distance from Centre Line	
	Calibration Date	
	Location	
	Height from Max Load Line	
	Height from Deck Installed On	
Anemometer 2	Distance from Bow	
	Anemometer Model / Manufacturer / Serial Number	
	Distance from Centre Line	
	Calibration Date	
	Location	
	Height from Max Load Line	
	Height from Deck Installed On	
Anemometer Usage	Distance from Bow	
Anemometer Height		Replaced by heights for individual instruments after 19xx
Wind Wave Observing Height		
Other Instrument 1		
Other Instrument 2		
Other Instrument 3		
Other Instrument 4		
Other Instrument 5		
Other Instrument 6

Table 3. List of major metadata elements checked

Ship name	Thermometer Type
Callsign	Thermometer Exposure
IMO Number	Thermometer Height
Recruiting Country	Hygrometer Type
Length	Hygrometer Exposure
Breadth	SST Method
Freeboard	SST Depth
Draft	Barograph Type
Cargo Height	Anemometer Height from Max Load Line
Distance from Bow to Bridge	Anemometer Height from Deck
Vessel Type	Anemometer Distance from Bow
Barometer Type	Visual Wind Wave Observing Height
Barometer Height	Platform Height

Table 4. List of metadata elements used in calculating completeness of records
