Note : much of the hydrometric data featured in this report is provisional; the Foot and Mouth outbreak has also restricted the amount of data available.

## Hydrological summary for the United Kingdom <br> <br> General

 <br> <br> General}Across much of the UK hydrological conditions in April would have been viewed as remarkable in any context other than that of the preceding seven months. Rainfall was again well above average for England and Wales and, although flooding did not approach the scale of that experienced in Oct-Dec 2000, many additional runoff records were established, reinforcing the recent redefinition of high flow regimes, especially in southern Britain. Similarly, unprecedented groundwater levels characterised many of the slower responding aquifer units - following the most outstanding groundwater recharge season of modern times. Parts of Scotland have been dry over the last five months but accumulated rainfall totals for most regions of the UK remain remarkably high. This is reflected in the overall reservoir stocks for England and Wales - currently around $97 \%$ of capacity (for the fourth May in succession) and the water resources outlook - generally - is exceptionally healthy.

## Rainfall

The relentless passage of low pressure systems since the early autumn of 2000 - most tracking across central and southern Britain - continued in April. Generally, rainfall was well distributed through the month and whilst parts of northern Scotland (the Western Isles in particular) and Northern Ireland reported below average rainfall, most of England and Wales exceeded $150 \%$ with an especially wet zone trending south-east from the Mersey estuary. Although April was much wetter in 1998 and 2000, the 2001 total still ranks amongst the wettest half dozen for England and Wales since 1935. Nonetheless, the monthly total was substantially lower than for each of the final four months of 2000 - testimony to the extraordinary precipitation patterns experienced over the recent past. Accumulated rainfall over the Jan-April period (for E\&W) was very much lower than for the preceding four months but it is still the wettest start to a year since 1951. More notably, the Sept 2000-April 2001 rainfall total exceeds the previous highest in this timeframe by a very wide margin. It also establishes a new wettest eight-month sequence for $\mathrm{E} \& \mathrm{~W}$ in a series from 1766 - again, clearly eclipsing the previous maximum. Over this timespan, rainfall in parts of the South-East are comparable with those of the Highland Region of Scotland - a rare circumstance.

## River flow

Catchments remained saturated through most of April and spates early in the month provided modest echoes of the flooding through the preceding autumn and winter. Generally however, April was notable for the maintenance of exceptionally high river flows rather than the incidence of severe flooding. By the second week of the month, brisk recessions had become established in most northern and western rivers and depressed monthly runoff totals characterised a few impermeable catchments (e.g. the River Ewe and, in Northern Ireland, the River Bush). In stark contrast, rivers sustained primarily from groundwater remained near to bankfull with mean flows commonly more than twice the April average. Many lowland rivers in England established new maximum April runoff totals - including the Thames in a record from 1883; unprecedented April totals were also reported for some more responsive rivers, e.g. the Dove, Lymington (Hants) and Kenwyn. Since the early autumn
the period over which near bankfull (or higher) flows have been maintained is truly exceptional - without precedent in the 118-year record for the Thames. Correspondingly, accumulated runoff totals testify to the singular nature of runoff in the recent past. Runoff totals for the period since last September are the highest on record for any 7month sequence for the great majority of gauging stations in England and Wales (plus some others) - with accumulated runoff around twice the annual average in some south-eastern catchments. Accumulated runoff totals are outstanding in many areas over timespans extending beyond three years.

## Groundwater

Accelerating evaporative demands in lateApril/early May - and the associated development of soil moisture deficits - may (in the east) have signalled the end of the most productive recharge season on record. Effective rainfall totals of two to three times the average for April contributed to recharge totals since the early autumn which are unprecedented over very wide areas. Groundwater levels in the more responsive Chalk outcrops fell during April but wells and boreholes with levels still clearly above pre-2000 maxima exhibited a wide distribution. Levels remain exceptional in the Magnesian Limestone and continue to rise throughout parts of the Permo-Triassic sandstones. In many boreholes the range of recorded variation has been significantly extended over the last four months (e.g. at Heathlanes); At Weeford Flats, the borehole was dry in early 1999 but levels are now approaching the long term maximum in a series from 1966. The extremely high groundwater levels have sustained unprecedented flows in spring-fed rivers (e.g. the Ewelme Brook which drains from the Chilterns), and been associated with widespread 'clearwater' flooding (in southern England especially). Significant flows have been noted in many 'dry' valleys and, locally, drainage systems have been overwhelmed; significant basement flooding and transport disruption have been persistent problems. A brisk decline in groundwater levels may now be anticipated but the water supply outlook for the summer and autumn remains very healthy.

The monthly rainfall figures* are copyright of The Met. Office and may not be passed on to any unauthorised person or organisation. All monthly totals since December 1998 are provisional (see page 12). The return period estimates are based on tables provided by the Meteorological Office (see Tabony, R.C., 1977, The variability of long duration rainfall over Great Britain, Scientific Paper No. 37) and relate to the specified span of months only (return periods may be up to an order of magnitude less if $n$-month periods beginning in any month are considered); RP estimates for Northern Ireland are based on the tables for north-west England. The tables reflect rainfall over the period 1911-70 and assume a stable climate. Artifacts in the England \& Wales and Scotland rainfall series can exaggerate the relative wetness of the recent past. "See page 12. The rainfall figures presented here are derived from different raingauge networks to those used to derive the CRU data series (now updated by the Hadley Centre).

## Rainfall accumulation maps

Whilst south-eastern regions of Britain have been very wet over the January-April period, Northern Ireland has had its driest start to the year since 1964; parts of western Scotland have been exceptionally dry also. Regional rainfall totals for the last twelve months serve to emphasise the recent moderation in the normal NW/SE gradient across the country: Scotland had its second driest May-April period in the last 16 years whereas the Thames Valley (most of the South-East also) registered its highest 12-month total, in this timeframe, in a catchment rainfall series from 1883.

## River flow 。 . .River flow.

## River flows - April 2001

*Comparisons based on percentage flows alone can be misleading. A given percentage flow can represent extreme drought conditions in permeable catchments where flow patterns are relatively stable but be well within the normal range in impermeable catchments where the natural variation in flows is much greater. Note: the period of record on which these percentages are based varies from station to station.

## River flow

 River flow

## Monthly river flow hydrographs

The river flow hydrographs show the monthly mean flow (bold trace), the long term average monthly flow (dotted trace) and the maximum and minimum flow prior to 1998 (shown by the shaded areas). Monthly flows falling outside the maximum/minimum range are indicated where the bold trace enters the shaded areas.

## River flow . . . River flow

| Dee | 146 | $63 / 63$ |

## Groundwater . . . Groundwater

Groundwater levels normally rise and fall with the seasons, reaching a peak in the spring following replenishment through the winter (when evaporation losses are low and soil moist). They decline through the summer and early autumn. This seasonal variation is much reduced when the aquifer is confined below overlying impermeable strata. The monthly max., min. and mean levels are displayed in a similar style to the river flow hydrographs. Note that most groundwater levels are not measured continuously - the latest recorded levels are listed overleaf.

[^0]

Groundwater levels April / May 2001

| Borehole | Level | Date | Apr.av. |  | Borehole | Level | Date | Apr.av. | Borehole | Level | Date |
| :--- | ---: | ---: | ---: | :--- | ---: | :--- | ---: | :--- | ---: | ---: | ---: |
| Apr. av. |  |  |  |  |  |  |  |  |  |  |  |

## Groundwater . . . Groundwater

## Groundwater levels - April 2001

The rankings are based on a comparison between the average level in the featured month (but often only single readings are available) and the average level in each corresponding month on record. They need to be interpreted with caution especially when groundwater levels are changing rapidly or when comparing wells with very different periods of record. Rankings may be omitted where they are considered misleading.
(Note: Redbank is affected by groundwater abstraction)

## Guide to the variation in overall reservoir stocks for England and Wales

## Comparison between overall reservoir stocks for England and Wales in recent years

## Location map... Location map

# National Hydrological Monitoring Programme 

The National Hydrological Monitoring Programme was instigated in 1988 and is undertaken jointly by the Centre for Ecology and Hydrology, Wallingford (formerly the Institute of Hydrology - IH ) and the British Geological Survey (BGS). Financial support for the production of the monthly Hydrological Summaries is provided by the Department of the Environment, Transport and the Regions, the Environment Agency (EA), the Scottish Environment Protection Agency (SEPA), the Rivers Agency (RA) in Northern Ireland, and the Office of Water Services (OFWAT).

## Data Sources

River flow and groundwater level data are provided by the regional divisions of the EA (England and Wales) and SEPA (Scotland), data for Northern Ireland are provided by the Rivers Agency and the Department of the Environment (NI). In all cases the data are subject to revision following validation (flood and drought data in particular may be subject to significant revision).

Reservoir level information is provided by the Water Service Companies, the EA, the West of Scotland and East of Scotland Water Authorities, and the Northern Ireland Water Service.

The National River Flow Archive (maintained by CEH Wallingford) and the National Groundwater Level Archive (maintained by BGS) provide the historical perspective within which to examine contemporary hydrological conditions.

## Rainfall

Most rainfall data are provided by The Met. Office (address opposite). To allow better spatial differentiation the rainfall data for Britain are presented for the regional divisions of the precursor organisations of the EA and SEPA. Following the discontinuation of The Met. Office's CARP system in July 1998, the areal rainfall figures have been derived using several procedures, including initial estimates based on MORECS*. Recent figures have been produced by The Met. Office, National Climate Information Centre (NCIC), using a technique similar to CARP. An initiative is underway with The Met. Office to provide more accurate areal figures and, since October 1999, to include more raingauges in the analysis. A significant number of additional monthly rainfall totals are currently being provided by the Environment Agencies; over the coming months further monthly
raingauge totals will be included for selected regions. Until the access to these additional data has stabilised the regional figures (and the return periods associated with them) should be regarded as a guide only.
*MORECS is the generic name for the Meteorological Office services involving the routine calculation of evaporation and soil moisture throughout Great Britain.

The National Hydrological Monitoring Programme depends on the active cooperation of many data suppliers. This cooperation is gratefully acknowledged; the Hydrological Summaries for the autumn and early winter of 2000/2001, in particular, stand as a testimony to the assistance provided by many hydrometric personnel working in exceptionally challenging circumstances.

## Subscription

Subscription to the Hydrological Summaries costs $£ 48$ per year. Orders should be addressed to:

[^0]:    * No March / April / May groundwater levels available.

[^1]:    Details of the individual reservoirs in each of the groupings listed above are available on request. The featured reservoirs may not be
    representative of the storage conditions across each region; this can be particularly important during droughts. The minimum storage figures relate to the 1988-2000 period only (except for West of Scotland where data commence in 1994). In some gravity-fed reservoirs (e.g. Clywedog) stocks are kept below capacity during the winter to provide scope for flood attenuation purposes.
