# Hydrological Summary for Creat Britain 

## JANUARY 1997

## Rainfall

January was cold - notably so early in the month - and remarkably dry in almost all regions. Light drizzle and fog were common in some areas but substantial frontal precipitation was rare. Many localities registered more than 25 days without significant rainfall - continuing a dry spell which began in mid-December. Coming at what, on average, is one of the wettest periods of the year, this produced a sharp deterioration in the water resources outlook. Many raingauges recorded new minimum January totals and for a significant minority including Plynlimon (central Wales) - it was the driest month on record. Scotland aside, all regions recorded $<25 \%$ of the January average; much of Wales and the North-West registered below $10 \%$. For Britain as a whole, it was the driest January in a 138 -year series; only in 1850 and 1880 have rainfall totals been similarly meagre for England and Wales in the last 200 years. As significantly, the combined Dec.- Jan. total was the second lowest in the last 116 years. This intensification of the drought has increased the already very large longer term rainfall deficiencies. In the Mar.-Jan. timeframe both 1995/96 and 1996/97 rainfall totals rank amongst the four driest such sequences for $\mathrm{E} \& \mathrm{~W}$ in more than 140 years; the April 95 - January 97 rainfall total is the lowest for any 22 -month accumulation since the 1850 s. Extreme drought conditions characterise parts of the NW England where the accumulated shortfall is the equivalent of more than seven month's rainfall. Severe long term drought conditions extend across most regions of E\&W apart from the South-West.

## River Flow

Early January saw a continuation of the recessions which became well established over the second half of December. Frozen catchments produced exceptionally depressed runoff rates which were commonly maintained throughout the month. Snowmelt provided a minor but useful contribution to runoff in some rivers (eg the River Lud) but a majority of the larger index rivers established new January minimum flows - most notably the Thames, Severn, Welsh Dee and Tay in flow records of 115, 76, 60 and 45 years respectively. In almost all regions January runoff totals were typical of an average August and some (especially in Wales and NW England) fell well below the late summer average. Preliminary analyses suggest that the January outflow from Britain was the lowest this century (closely approached only by 1963 and 1964). Accumulated runoff totals, particularly in the 10-22 month timeframes, are now close to or below previous minima.

In the 20 -month timespan a few southern rivers (including the Gt Stour and Sussex Ouse) reported unprecedented totals for any start month. In the English lowlands the protracted decline in baseflows and the associated failure of winterbournes has focused concern on the potential contraction of the headwater stream network - and the consequential loss of aquatic habitat over the coming summer.

## Groundwater

On average, infiltration rates peak in January but this year has seen very little replenishment to any major aquifer. After modest recoveries in late 1996, recessions have recommenced throughout most of the PermoTriassic sandstones outcrop areas and January levels were commonly the lowest on record. With 1996/97 recharge (thus far) to the Chalk less than $20 \%$ of average over wide areas groundwater levels are also very depressed - especially in the northern outcrops. To the south, levels are generally close to the seasonal minimum but a little healthier in the west. Only rarely most recently in 1992 - have water-tables been so depressed in late winter across so many aquifers. Modest - but seasonally high - early February soil moisture deficits in the English lowlands underline the narrowing window of opportunity for further recharge before evaporation rates accelerate in the spring. A notably wet late spring is needed to extend the recharge season and delay the onset of the 1997 summer recessions.

## General

Severe and protracted drought conditions now extend across most of England and Wales. Overall reservoir stocks declined appreciably in January and are very substantially below average for the late winter (but still a little healthier than early in 1996). Given above average late winter/spring rainfall there is still time for overall surface water stocks to approach capacity in most areas. Prospects for groundwater are less encouraging. However, groundwater resources have demonstrated their resilience in a number of recent drought years and much will depend on summer rainfall and demand patterns. A repetition of the weather conditions experienced during the spring and summer of 1990 or 1995 would result in extremely low river flows and groundwater levels requiring very careful management to reconcile water supply demands with the competing needs of the aquatic environment.

British Geological

Data for this report have been provided principally by the regional divisions of the newly formed Environment Agency (England and Wales) and the Scottish Environment Protection Agency. For reasons of consistency and to provide greater spatial discrimination, the original regional divisions of the precursor organisations have been retained for use in the Hydrological Summaries. The majority of the areal rainfall figures have been provided by the Meteorological Office. Figure 3 is based on weather data collected by the Institute of Hydrology at Wallingford, Balquhidder (Central Region, Scotland) and Plynlimon. Reservoir contents information has been supplied by the Water Services Companies, the Environment Agency and, in Scotland, West of Scotland Water Authority and East of Scotland Water.

The most recent areal rainfall figures are derived from a restricted network of raingauges and a proportion of the river flow data is of a provisional nature.

A map (Figure 4) is provided to assist in the location of the principal monitoring sites.
Financial support towards the production of the Hydrological Summaries is given by the Department of the Environment, the Environment Agency, the Scottish Environment Protection Agency and the Office of Water Services (OFWAT).

The Hydrological Summaries are available on annual subscription at a current cost of $£ 48$ per year enquiries should be directed to the National Water Archive Office at the address below. No charge is made to those organisations providing data for the Summaries. The text of the monthly report, together with details of other National Water Archive facilities, is available on the World Wide Web: http://www.nwl.ac.uk:80/ ~nrfadata/nwa.html

## MORECS

Most of the recent monthly regional rainfall data featured in the Hydrological Summaries are MORECS assessments. MORECS is the generic name for The Meteorological Office services involving the calculation of evaporation and soil moisture routinely for Great Britain. Products include a weekly issue of maps and tables of potential and actual evaporation, soil moisture deficits, effective rainfall and the hydrometeorological variables used to calculate them. The data are used to provide values for 40 km squares - or larger areas - and various sets of maps and tables are available according to user requirements. Options include a day-by-day retrospective calculation of soil moisture at any of 4000 raingauge sites.

Further information about MORECS services may be obtained from: The Meteorological Office, Sutton House, London Road, Bracknell, RG12 2SY

Note: The monthly regional rainfall figures for England and Wales for December 1996 \& January 1997 correspond to the MORECS areal assessments derived by the Meteorological Office. In northern England these initial assessments may have a particularly wide error band associated with them, especially when snow is a significant component in the precipitation total. The figures for the Scottish regions (and also for Scotland) for December 1996 \& January 1997 were derived by IH in collaboration with the SEPA regions. The provisional figures for England and Wales and for Scotland are derived using a different raingauge network. Regional areal rainfall figures are regularly updated (normally one or two months in arrears) using figures derived from a far denser raingauge network.

LTA refers to the period 1961-90.
Return period assessments are based on tables provided by the Meteorological Office*. The tables reflect rainfall totals over the period 1911-70 only and the estimate assumes a sensibly stable climate. They assume a start in a specified month; return periods for a start in any month may be expected to be an order of magnitude less - for the longest durations the return period estimates converge. "Wet" return periods underlined. The ranking of accumulated rainfall totals for England \& Wales and for Scotland can be affected by artifacts in the historical series - on balance these tend to exaggerate the relative wetness of the recent past.

Notes:
(i) Values based on gauged flow data unless flagged (natr.), when naturalised data have been used.
(ii) Values are ranked so that lowest runoff is rank 1.
(iii) \%LT means percentage of long term average from the start of the record to 1995. For the lang periods (at the right of this table), the end date for the long term is 1997.

Live or usable capacity (unless indicated otherwise) *Gross storage/percentage of gross storage

1. Includes Haweswater, Thirlmere, Stocks and Barnacre.

Cow Green, Selset, Grassholme, Balderhead, Blackton and Hury. Howden, Derwent and Ladybower.
Swinsty, Fewston, Thruscross and Eccup.
The Nidd/Barden group (Scar House, Angram, Upper Barden, Lower Barden and Chelker) plus Grimwith.
6. Lower Thames (includes Queen Mother, Wraysbury, Queen Mary, King George VI and Queen Elizabeth II) and Lee Valley (includes King George and William Girling) groups -pumped storages.
7. Farmoor 1 and 2 -pumped storages.
8. Blagdon, Chew Valley and others.
9. Roadford began filling in November 1989.
10. Shared between South West (river regulation for abstraction) and Wessex (direct supply).
11. Usk, Talybont, Llandegfedd (pumped stroage), Taf Fechan, Taf Fawr.
12. Claerwen, Caban Coch, Pen-y-garreg and Craig Goch.
13. Megget, Talla, Fruid, Gladhouse, Torduff, Clubbiedean, Glencorse,Loganle and Morton (upper and lower).
14. Thorters, Donolly, Stobshiel, Lammerloch, Hopes and Whiteadder

A GUIDE TO THE VARIATION IN OVERALL RESERVOIR STOCKS FOR ENGLAND AND WALES

A COMPARISON BETWEEN OVERALL RESERVOIR STOCKS FOR england and wales in recent years

These plots are based on the reservoirs featured in Table 4 only

Note: Variations in storage depend on the balance between inputs (from catchment rainfall and any pumping) and outputs (to supply, compensation flow, HEP, amenity). There will be additional losses due to evaporation, especially in the summer months. Operational strategies for making the most efficient use of water stocks will further affect reservoir storages. Table 4 is intended to provide a link between the hydrological conditions described elsewhere in the report and the water resources situation. The reservoirs featured may not be representative of storage conditions across the individual regions; this can be particularly important during drought conditions (eg, in the Severn-Trent region during 1995/96).

The Institute of Hydrology Meteorological Station occupies a relatively open site on the Thames floodplain about 5 km NW of the Chilterns escarpment. Station elevation is 48 m

Balquhidder
Daily Rainfall

Hourly Temperature

Hourly Wind Speed

Hourly Wind Direction

The Lower Kirkion automatic weather station (Balquhidder) occupies a relatively sheltered position at the mouth of the SSE trending Kirkton Glen. Station elevation is 270m aOD and average annual rainfall exceeds 2000 mm ; snow cover is expected for $10-30$ days a year.

## FIGURE 3 (continued)

FIGURE 3a. WALLINGFORD SMD DATA 1996/7.

## Plynlimon

Hourly Wind Direction

The Dolydd automatic weather station at Plynlimon is sited in an exposed field with a forested area to the south. Surrounding land reaches a peak height of around 400 m . Station elevation is 300 m aOD and average annual rainfall exceeds 2300 mm .

Depth below surface: 0-0.325m

Depth below surface: $0.325-1.0 \mathrm{~m}$

Daily Rainfall

## Note

Soil moisture deficit is defined as the amount by which the water stored in the soil is below the quantity held at field capacity. Two automatic soil water stations (ASWSs) deployed at Wallingford, which use capacitance soil water sensors installed at depths of 5,15 and 50 cm , are the sources of the data. Figure 3a shows deficits calculated from one of the stations for the depth ranges $0-0.325 \mathrm{~m}$ ( 15 cm probe) and $0.325-1.0 \mathrm{~m}$ ( 50 cm probe) at 0100 GMT on each day. At the end of January 1996, field capacity was re-estimated using recent data and the soil moisture deficit values for the previous months were recalculated accordingly.

Daily rainfall from the Wallingford met station from February 1996 is presented.
