

Hydrological Summary for Great Britain

JANUARY 1994

Rainfall

For most areas, January was a mild and very unsettled month; weather patterns were, like December, dominated by a continuing sequence of Atlantic frontal systems. Rainfall amounts decreased somewhat over the second fortnight and, overall, sunshine totals were notably high in parts of central England. January rainfall totals were above the 1961-90 mean - generally by a substantial margin. In the winter thus far, southern Britain has recorded remarkably few dry days but daily rainfall totals in January were moderate in most areas. Exceptions included the South Downs where in some localities totals reached 200 mm over the five weeks ending in mid-January, equivalent to around 40% of the annual average for some raingauges. For England and Wales as a whole, the combined Dec/Jan rainfall total is amongst the ten highest in the full series from 1767 (and closely comparable to 1989/90). In the English lowlands accumulated rainfalls are even more exceptional in the five-month timeframe. Provisional rainfall figures suggest that for many catchments the Sep-Jan rainfall total was the highest or second highest (after 1960/61) for at least 50 years. Equally notable for the Anglian region is the accumulated rainfall total over the last 19 months; the associated return period testifies to a remarkable transformation relative to the preceding sustained drought. Long term deficiencies in the English lowlands are now trivial at the regional scale. Importantly, the abundant lowland rainfall, 25-30% above average since June 1992, translates into much larger proportional increases in rates of runoff and aquifer recharge.

River Flow

1994 began with widespread flood warnings and substantial floodplain inundations in southern Britain. Protracted sequences of near-bankfull flows typified large parts of southern Britain in January - spates were common but relatively minor in most of northern Britain. Many new monthly flow records were established in January but generally accumulated runoff totals were more outstanding than individual flood peaks which mostly had associated return periods of less than 5-10 years. However, with headwater springs flowing very strongly, the Lavant winterbourne in the South Downs, which was dry throughout the great majority of 1992, burst its banks on the 4th January heralding very persistent flooding in the Chichester area; transport disruption was severe. Provisional data suggest that

maximum January runoff totals were registered for around half the rivers in eastern and southern England. For a substantial number (mostly benefitting from heavy baseflow) including the Lud, Mimram and Kennet the monthly runoff was unprecedented; in others, January 1994 ranks second only to February 1990. Accumulated runoff totals for the period beginning in the autumn are also outstanding in the English lowlands and, given the magnitude of recent runoff, the limited flooding testifies to the moderating influence of the relatively even distribution of rainfall.

Groundwater

Weather conditions have remained conducive to heavy groundwater recharge, in southern England particularly, over much of the last ten weeks. Late winter levels in the Chalk are indicative of recoveries, from last summer, of around twice the average annual range over wide areas. In some districts, parts of the South Downs in particular, percolation was limited only by the remarkably steep water-table rises which produced artesian conditions in mid-January. The Chilgrove well (north of Chichester) began overflowing in the 7th for the first time since 1960 and the extraordinary recent abundance of recharge is confirmed by the record maximum registered at nearby Compton - in a record from 1894. The Holt borehole in the Chilterns also surpassed its previous maximum and index well levels are near, or at, seasonal maxima throughout the great majority of the Chalk and some of the southern Permo-Triassic outcrops. Water levels in parts of the slow-responding confined Permo-Triassic sandstones in the Midlands are still below average but rising steadily. Very steep winter recoveries typify other aquifers also (see, for example, the Alstonfield and New Red Lion hydrographs) and there are few, if any, modern parallels to the transformation in overall groundwater resources since the summer of 1992.

General

Overall water stocks are exceptionally healthy and hydrological stress may be expected to focus rather more on flood vulnerability over the remainder of the winter. Notwithstanding the saturated catchments however, the spring of 1990 provides a reminder that, on rare occasions, the water resources outlook can deteriorate surprisingly quickly.

British
Geological
Survey

Data for this report have been provided principally by the regional divisions of the National Rivers Authority* in England and Wales, the River Purification Boards in Scotland and by the Meteorological Office. Reservoir contents information has been supplied by the Water Services Companies, the NRA or, in Scotland, the Lothians Regional Council. The most recent areal rainfall figures are derived from a restricted network of raingauges and a proportion of the river flow data is of a provisional nature.

A map (Figure 3) is provided to assist in the location of the principal monitoring sites.

Financial support towards the production of the Hydrological Summaries is given by the Department of the Environment and the National Rivers Authority.

The Hydrological Summaries are available on annual subscription at a current cost of £48 per year - enquiries should be directed to the National Water Archive Office at the address below. No charge is made to those organisations providing data for the Summaries.

* For reasons of consistency and to provide greater spatial discrimination, the original ten regional divisions of the NRA have been retained for use in the Hydrological Summaries.

MORECS

The recent monthly regional rainfall data featured in the Hydrological Summaries are MORECS assessments. MORECS is the generic name for The Meteorological Office services involving the calculation of evaporation and soil moisture routinely for Great Britain. Products include a weekly issue of maps and tables of potential and actual evaporation, soil moisture deficits, effective rainfall and the hydrometeorological variables used to calculate them. The data are used to provide values for 40 km squares - or larger areas - and various sets of maps and tables are available according to user requirements. Options include a day-by-day retrospective calculation of soil moisture at any of 4000 rain-gauge sites.

Further information about MORECS services may be obtained from: The Meteorological Office, Sutton House, London Road, Bracknell, RG12 2SY

Note: The monthly rainfall figures for the NRA regions for January correspond to the MORECS areal assessments derived by The Meteorological Office. In northern Britain these initial assessments may have a wide error band associated with them. The figures for the RPB regions for January were derived by IH in collaboration with the RPBs. The provisional figures for England and Wales and for Scotland are derived using a different raingauge network. Regional areal rainfall figures are regularly updated (normally one or two months in arrears) using figures derived from a far denser raingauge network.

	% LTA	96	2-5	99	<2	112	<u>5-10</u>	114	<u>50-80</u>

LTA refers to the period 1961-90.

Return period assessments are based on tables provided by the Meteorological Office*. The tables reflect rainfall totals over the period 1911-70 only and the estimate assumes a sensibly stable climate. They assume a start in a specified month; return periods for a start in any month may be expected to be an order of magnitude less - for the longest durations the return period estimates converge. "Wet" return periods underlined.

* Tabony, R.C., 1977, The Variability of long duration rainfall over Great Britain, Scientific Paper No. 37, Meteorological Office.

Notes: (i) Values based on gauged flow data unless flagged (natr.), when naturalised data have been used.
(ii) Values are ranked so that lowest runoff as rank 1.
(iii) %LT means percentage of long term average from the start of the record to 1992. For the long periods (at the right of this table), the end date for the long term is 1993.

TABLE 4 START-MONTH RESERVOIR STORAGES UP TO FEBRUARY 1994

Area	Reservoir (R)/ Group (G)	Capacity● (MI)	1993				1994		1993
			Sep	Oct	Nov	Dec	Jan	Feb	Feb
North West	Northern Command Zone ¹	(G) 133375	58	51	42	44	80	97	98

● Live or usable capacity (unless indicated otherwise)

+ Megget reservoir held at 75% capacity for repairs

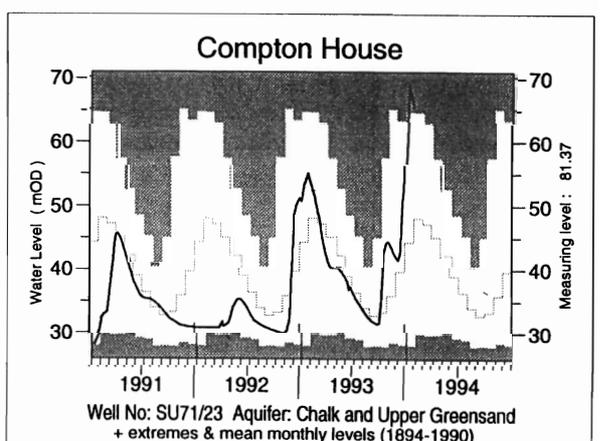

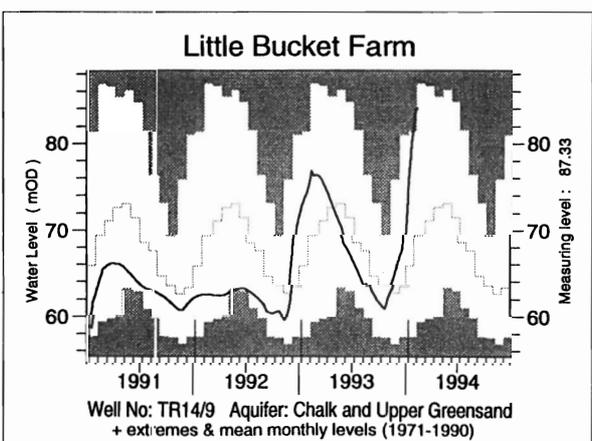

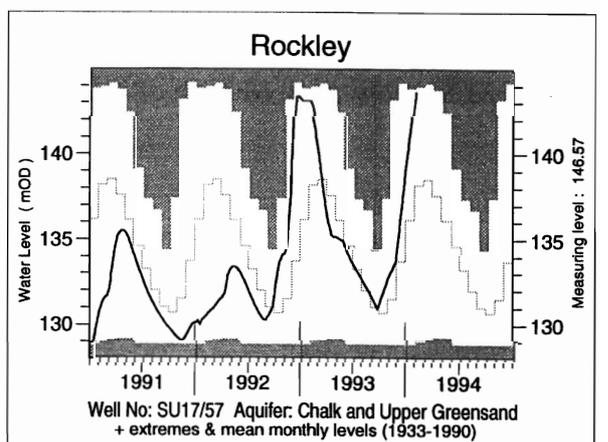

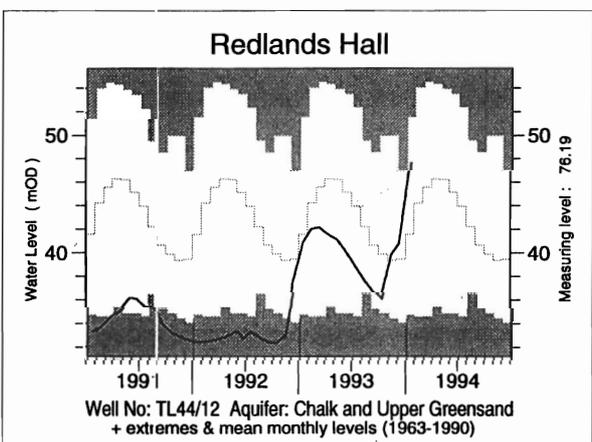

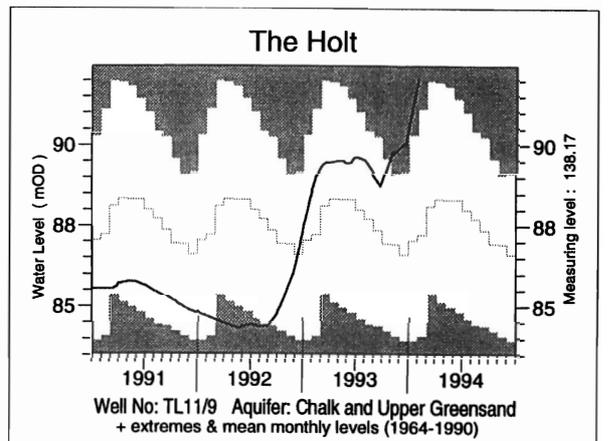

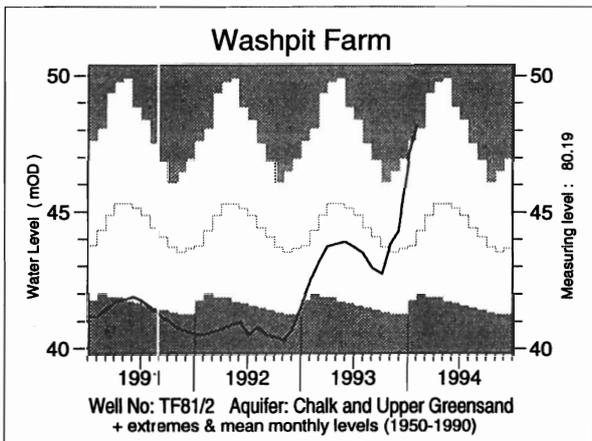

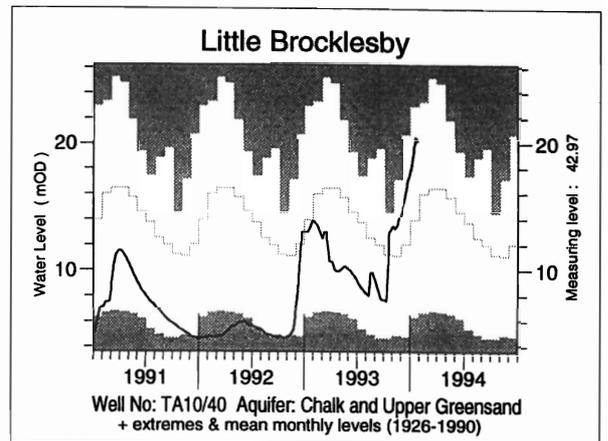

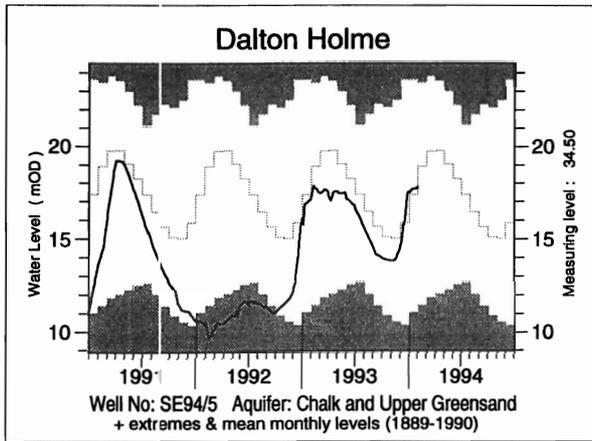

* Gross storage/percentage of gross storage

1. Includes Haweswater, Thirlmere, Stocks and Barnacre.
2. Cow Green, Selset, Grassholme, Balderhead, Blackton and Hury.
3. Howden, Derwent and Ladybower.
4. Swinsty, Fewston, Thruscross and Eccup.
5. The Nidd/Barden group (Scar House, Angram, Upper Barden, Lower Barden and Chelker) plus Grimwith.
6. Lower Thames (includes Queen Mother, Wraybury, Queen Mary, King George VI and Queen Elizabeth II) and Lee Valley (includes King George and William Girling) groups - pumped storages.
7. Farmoor 1 and 2 - pumped storages.
8. Blagdon, Chew Valley and others.

9. Shared between South West (river regulation for abstraction) and Wessex (direct supply).
10. Usk, Talybont, Llandegfedd (pumped storage), Taf Fechan, Taf Fawr.
11. Claerwen, Caban Coch, Pen y Garreg and Craig Goch.

Note: Variations in storage depend on the balance between inputs (from catchment rainfall and any pumping) and outputs (to supply, compensation flow, HEP, amenity). There will be additional losses due to evaporation, especially in the summer months. Operational strategies for making the most efficient use of water stocks will further affect reservoir storages. Table 4 provides a link between the hydrological conditions described elsewhere in the report and the water resources situation.

FIGURE 2 GROUNDWATER LEVEL HYDROGRAPHS
