

SUMMARY

The outlook for October and for the October–December period is for below normal river flows in central, eastern and southern England. Elsewhere, river flows are likely to be in the normal range. Groundwater levels for October are likely to be normal to below across the country, and exceptionally low in southern England. Over the three-month period, levels are expected to return to the normal range.

Rainfall

Rainfall in September was above average for the UK as a whole, particularly in Northern Ireland, eastern Scotland and south-east England. Elsewhere, areas of western Scotland, Wales and East Anglia received below average rainfall.

The rainfall outlook (issued by the Met Office on 29.09.2022) for October and October–December suggests average rainfall is likely over these timeframes, although for the three-month period there is a slight increase in the likelihood of dry conditions and precipitation will also be skewed towards western and northern areas.

River flows

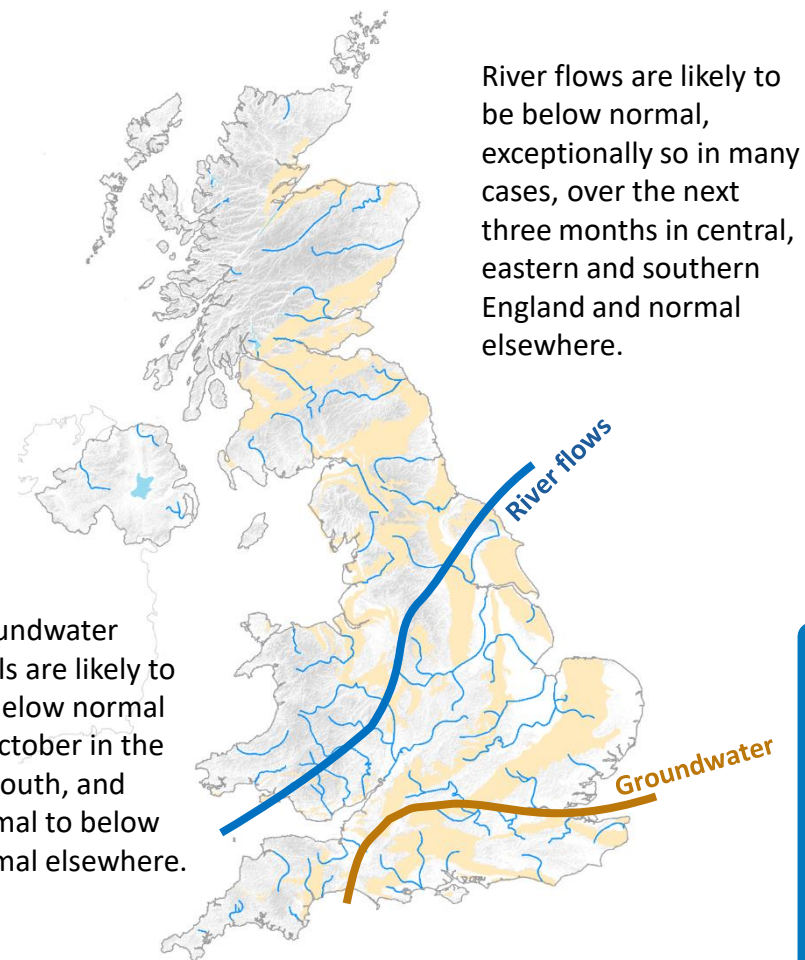

River flows in September were below normal across most of the country, with normal range flows constrained to parts of northern England and Scotland. Across much of England and Wales, flows were notably or exceptionally low and the lowest on record in some cases.

River flows in October and for October–December are likely to continue to be below normal with a likelihood of exceptionally low flows in parts of central and southern England. In northern Britain, flows are likely to be in the normal range.

Groundwater

Groundwater levels in September were normal to below normal across all aquifers, with notably and occasionally exceptionally low levels in the far south.

Groundwater levels in October are likely to be normal to below normal and in southern England, below normal with exceptionally low levels persisting in some boreholes. The three month outlook suggests a similar picture, but with levels tending towards normal, although this is dependent on rainfall and the start of the recharge season.

Shaded areas show principal aquifers

The Hydrological Outlook UK provides an outlook for the water situation for the UK over the next three months and beyond. For guidance on how to interpret the outlook, a wider range of information, and a full description of underpinning methods, please visit the website: www.hydroutuk.net

About the Hydrological Outlook:

This document presents an outlook for the UK water situation for the next 1 – 3 months and beyond, using observational datasets, meteorological forecasts and a suite of hydrological modelling tools. The outlook is produced in a collaboration between the UK Centre for Ecology and Hydrology (UKCEH), British Geological Survey (BGS), the Met Office, the Environment Agency (EA), Natural Resources Wales (NRW), the Scottish Environment Protection Agency (SEPA), and for Northern Ireland, the Department for Infrastructure – Rivers (DfIR).

Data and Models:

The Hydrological Outlook depends on the active cooperation of many data suppliers. This cooperation is gratefully acknowledged. Historic river flow and groundwater data are sourced from the UK National River Flow Archive and the National Groundwater Level Archive. Contemporary data are provided by the EA, SEPA, NRW and DfIR. These data are used to initialise hydrological models, and to provide outlook information based on statistical analysis of historical analogues.

Climate forecasts are produced by the Met Office. Hydrological modelling is undertaken by UKCEH using the Grid-to-Grid, PDM and CLASSIC hydrological models and by the EA using CATCHMOD. Hydrogeological modelling uses the R-groundwater model run by BGS and CATCHMOD run by the EA. Supporting documentation is available from the Outlooks website: <https://www.hydoutuk.net/about/methods>

Presentation:

The language used in the summary presented overleaf generally places flows and groundwater levels into just three classes, i.e. below normal, normal, and above normal. However, the underpinning methods use as many as seven classes as defined in the graphic to the right, i.e. the summary uses a simpler classification than some of the methods. On those occasions when it is appropriate to provide greater discrimination at the extremes the terminology and definitions of the seven class scheme will be adopted.

	Percentile range of historic values for relevant month
Exceptionally high flow	> 95
Notably high flow	87-95
Above normal	72-87
Normal range	28-72
Below normal	13-28
Notably low flow	5-13
Exceptionally low flow	< 5
