INTRODUCTION

The discovery by Consolidated Goldfields of the Gairloch Cu-Zn-Au deposit in 1983 was one of the more notable successes for mineral exploration in the United Kingdom (Jones et al., 1987). Integrated exploration outlined a severely deformed, but potentially economic, volcanic-hosted massive sulphide deposit (Besshi-style) within the Loch Maree Group near Gairloch. The work was concentrated over the Gairloch Schist Belt which forms the main outcrop of the Loch Maree Group on the western side of the Loch Maree Fault. Reconnaissance studies were carried out by Consolidated Goldfields over the Loch Maree Schist Belt to the east of the fault and also in the Scardroy area further to the south east (Jones et al., op. cit.) but the results of these studies were not presented in the published paper. As Besshi-style VMS deposits are often stratigraphically controlled and extend over long distances, further exploration was warranted in rocks of similar age. This open file report gives the results of a geochemical survey of the Scardroy area which was carried out by the British Geological Survey as part of the Mineral Reconnaissance Programme (MRP) for the Department of Trade and Industry. A brief introduction to the geology and regional geochemistry of the Scardroy area is given before the results of the MRP survey.

The Scardroy area is situated about 45 km to the south-east of Gairloch and about the same distance west of Inverness. It is drained by the rivers Meig and Corrin at the head of Strathconan but extends to the south west as far as Loch Monar (Figure 1). Most of the area is mountainous moorland given over to deer forest with a few coniferous plantations in the lower valleys.

REGIONAL GEOLOGY

The Lewisian rocks were mapped by the Geological Survey in 1913 as part of Sheet 82 Lochcarron (Peach et al., 1913) and form an irregular 'mushroom-like' shape with the base of the stem pointing down the River Meig valley by Loch Beannacharain. Smaller slices occur within the Moine south-east of the Strathconan fault. The Lewisian probably forms allochthonous basement slices caught up in the later Caledonian deformation and the irregular shape is the result of interference folds. The main rock types present in the inlier are fairly typical acid and hornblende gneisses and amphibolite but small outcrops of ultrabasic rock and metalimestone are also present (Sutton and Watson, 1953). The Moine rocks are composed of psammites and pelites which form part of the Morar and Glensinnan Divisions (Craig, 1983).

The area is cut by the major north-east - south-west trending fault zone of the Strathconan fault which extends from Loch Hourn on the western seaboard for 95 km to Carn Chuinneag. The other major fault in the area is shown as a discontinuous feature running north-west - south-east. This may be a

continuation of the similar trending Loch Maree fault and could well run down Loch Beannacharain and terminate against the Strathconon fault as suggested in the memoir (Hinxman p.83 in Peach et al., 1913) but not as shown on the geological map.

No mineralisation is recorded in the Survey memoir of the area, except for a mention of pyrite in graphitic schists in the Glen Strath Farrar inlier. Anderson states in one section of the memoir that they are comparable with pyritic graphite schist in the Dornie area which contain 'a very small amount of gold' (Sheet 71 Memoir).

REGIONAL GEOCHEMICAL DATA

Regional mapping of the Scardroy area was undertaken by the Geochemical Survey Programme (GSP) in 1974-75 as part of the systematic sampling of the Great Glen 1:250,000 map area (Johnstone et al., 1979 and BGS, 1987). On the north-east side of Loch Maree a prominent linear north-west trending zone of high Cu (up to 220 ppm) and, to a lesser extent, high Co, Ni and Zn is associated with the Loch Maree Group supracrustal schists and amphibolites. These are known to contain pyrite-chalcopyrite mineralisation on the north side of Loch Maree (Peach et al. 1907).

A possible extension of this anomalous zone south-eastward along the Loch Maree fault and into the Moine nappe can be identified from the coloured digital image presented in the Great Glen geochemical atlas (BGS, 1987). Within the 150 sq km project area, (Figure 2) six Cu values exceed 40 ppm, (maximum 102 ppm) and lie along a north-west - south-east trending linear feature. This runs sub-parallel to, but offset 1-2 km south-west of the main fault. A further anomalous site (63 ppm) directly overlies the fault [220375 852610]. The source of these copper anomalies appears to lie principally within tectonically emplaced Lewisian amphibolite and associated hornblendic gneiss. However, south-eastwards on the same trend, faulted and crushed Moine pelites give rise to a value of 89 ppm Cu at [220985 850335]. South-east of the termination of the Loch Maree fault against the Strathconon fault, two further anomalies (52, and 56 ppm) are associated with Lewisian acid and hornblende schist, and a third (61 ppm), with Moine pelites. All occur in rocks extensively crushed by movement along the Strathconon fault.

Follow-up stream sediment sampling generally confirmed the location of the original GSP anomalies, but with improved geochemical contrast and higher mean levels for most elements. In the upper reaches of the most anomalous catchment (Coire a' Bhuic), MRP sediments contain 82, 138 and 263 ppm Cu, compared with GSP samples from the same area with 43, 45, and 54 ppm Cu. This reflects in part differences in sampling and analysis, as GSP samples were dry screened to -150µm and analysed by Direct Reading Emission Spectrometry. However, some variation can be identified as the

result of sample site selection. For example, the GSP maximum Cu value of 102 ppm recorded from a poorly drained peaty area downstream of Loch Coire a' Bhuic was not reproduced in the MRP sampling (25 ppm).

MRP GEOCHEMICAL SURVEY

160 samples of heavy mineral concentrates and stream sediments were collected within the Scardroy area. Their location is shown on Figure 2. The concentrates were prepared by panning 4 litres of -2 mm sediment using the methods described by Gunn (1989). The stream sediments were prepared by wet sieving through a 150 µm nylon sieve using standard BGS techniques.

The concentrate samples were analysed for Ca, Ti, V, Mn, Fe, Co, Ni, Cu, Zn, Y, Zr, Nb, Ag, Sn, Sb, Ba, La, Ce, Pb, Th and U by X-Ray fluorescence spectrometry at the BGS Applied Geochemistry Group laboratory. Au was determined by Acme Analytical Laboratory using an AAS finish after MIBK extraction of an aqua regia attack on 10 g of sample. The stream sediment samples were analysed by XRF for Ca, Ti, V, Mn, Fe, Co, Ni, Cu, As, Zr, Nb, Mo, Ag, Sn, Sb, Ba, La, Ce, Pb, Bi, Th, and U by the same method.

Au anomalies

KLP 3559	225190	853680	220 ppb	Allt Glen Meinich
KLP 3605	223870	848110	4960 ppb	N side Strathconon fault
KLC 3571	222545	857015	67 ppb	Sgurr a'Choire rainich
KLC 3597	217812	848740	86 ppb	Meall Innis na Sine
KLC 3605	223870	848110	81 ppb	W side Strathconon fault
KLC 3642	219760	845120	54 ppb	River Orrin, E trib.

Cu anomalies

KLP 3541	220360	852600	49 ppm	Scardroy Burn, N side
KLC 3502	217080	851780	138 ppm	Coir' a'Bhuic
KLC 3504	216770	851770	263 ppm	Coir' a'Bhuic
KLC 3505	219570	851160	57 ppm	Allt Coir' a'Bhuic
KLC 3506	216690	851870	82 ppm	Coir' a'Bhuic
KLC 3530	218940	853360	55 ppm	Scardroy Burn, N side
KLC 3606	226680	848680	63 ppm	Creagan a Chaorain

The gold anomalies are clustered along the Strathconon fault in the streams draining into Glen Meinich (KL 3558, 3559, 3560, 3571) (Figures 3 and 4). The elevated Au levels in the Allt Gleann

Meinich probably demonstrate the effect of fluvial reworking and upgrading of glacial material. The original source of the Au may be within the Lewisian amphibolite which forms the northern flank of Sgurr a'Glas Leathaid (shown as spot height 844 m). The Strathconon fault is marked by a mile-wide zone of crushed and hematite-stained rock (Peach et al., 1913). The Au anomalies found in the streams adjacent to the fault are probably related to these crush zones. KLC 3597 with 86 ppb Au was collected from a stream draining a north-west - south-east crush zone which contained minor sulphides and some gossanous alteration in rock samples KLR 3667 and 3668. Minor Au-bearing mineralisation is recorded by Alderton (1988) in the vicinity of the Strathconan fault system in the Ratagain complex, 45 km to the south-west.

High Cu values in stream sediments are found in the Allt Coir' a'Bhuic confirming the pattern of the regional survey. The anomaly extends for 2.5 km downstream, and the three headwater streams draining Craig Coir' a'Bhuic (KLC 3502, 3504 and 3506) contain anomalous Cu. However, none of the panned concentrates from this area are anomalous. Detailed investigation of the exposures revealed the presence of chalcopyrite-bearing pyrrhotite bodies up to 4 m in thickness, hosted by Lewisian amphibolite. These sulphide bodies are strongly deformed and irregularly podiform in shape. Samples KLR 3669-3673 contain up to 2976 ppm Cu, 188 ppm Co, 176 ppm Ni, 991 ppm Zn and 12 ppm Ag. Minor Cu anomalies are found in Scardroy Burn, with values of about 50 ppm in one panned concentrate and stream sediment sample. The sample KLP 3530 was collected from a stream that drains the same amphibolite body as Allt Coir' a'Bhuic and there may be a similar sulphide body in the catchment.

Table 4 Major rock type code classifications

Scardroy Open File Report - Rock Codes

2170	Biotite schist
2200	Gneiss - undifferentiated
22EM	Garnet mica gneiss
2230	Hornblende gneiss
2270	Biotite gneiss
227E	Biotite garnet gneiss
2300	Granitic gneiss
2C00	Psammitic gneiss
2K00	Pelitic gneiss
3800	Breccia
493C	Quartz-carbonate vein
4H00	Iron oxide/hydroxide rock - 'gossan'
