THE CULTURE CENTRE OF ALGAE AND PROTOZOA

36 Storey's Way, Cambridge, CB3 0DT
Telephone: Cambridge (0223) 61378

Director	E. A. George, MA
Curator of Freshwater Algae	D. J. Hibberd, PhD
Assistants	D. R. Perdue, MPhil S. F. Cann
Curator of Marine Algae	J. H. Belcher, DSc
Assistants	N. C. Pennick, BSc J. P. Cann
Curator of Protozoa	F. C. Page, PhD
Assistants	S. M. Blakey, BSc L. Greer
Head of Electron Microscopy Section	E. M. F. Swale, DSc
Technician	K. J. Clarke
Head of Preservation Section	G. J. Morris, PhD

Requests for cultures or information should be addressed to the Director.

INTRODUCTION

This collection of cultures of algae and protozoa was started by E. G. Pringsheim in Prague and the first list, comprising 48 strains, was published in 1928. It was taken over by Cambridge University in 1947 and subsequently collections at the Universities of Indiana and Göttingen were started each with a nucleus of cultures from Cambridge. Cultures left behind in Prague by Pringsheim were built into another collection there. Thus, in many cases the same strain may be in several or all of these great collections; on the other hand, in spite of considerable interchange, no one collection maintains all available worthwhile strains. In April 1970, the collection was expanded to form the basis of the Culture Centre of Algae and Protozoa, a component body of the Natural Environment Research Council. In November 1975, the Centre was merged into the Institute of Terrestrial Ecology - another and much larger component body of NERC.

As well as algae and free-living protozoa, the Cambridge collection maintains a few other micro-organisms which are not easily available elsewhere, a number of bryophytes and at the moment one flowering plant, *Wolffia*, and one rotifer. The collection does not aim to include parasitic protozoa or the larger seaweeds.

EXPLANATORY NOTES ON THE LIST

Genera, and species within them, are arranged alphabetically. Algae, protozoa, and other micro-organisms are listed together first, then the bryophytes and higher plants. A systematic list of genera is given on page 9.

In general, unless a mistake has clearly been made, or the taxonomy has been revised, names are those given to the strain by the isolator. The main objective in compiling this list has been that of enabling workers who are not well versed in taxonomy and nomenclature to find what they want with the minimum of trouble.

This list must not be taken as an authority for names. Strains are listed under the name of the species, with the following information where available:-

- (a) The reference number in the collection, prefixed by 'L' if the culture is only available in liquid medium, and by 'B' if only with bacteria (agnotoxenic or monoxenic). In the absence of any such prefix, a strain may be assumed to be in pure (axenic) culture on an agar slope. 'N' indicates that the strain is preserved in liquid nitrogen (see Preservation below). An asterisk after a strain number (chiefly diatoms) indicates that the strain probably cannot be maintained indefinitely and may be replaced by a similar strain.
- (b) The name of the isolator and the year of isolation. Where two names are separated by a stroke, usually the first established the agnotoxic culture and the second rendered it axenic.
- (c) Any reference number given by the isolator, or by another collection in cases where the strain was obtained from it.
- (d) Any other information including an ecological note if other than fresh water, concluding with the country where the wild material was collected.

The absence of a strain or species from the list does not necessarily mean that it is not available. In some cases, we are able to obtain a strain from another collection.

Requests for organisms which lie outside the scope of CCAP should be made to other major culture collections in the United Kingdom.

OTHER CULTURE COLLECTIONS

Bacteria of industrial importance

National Collection of Industrial Bacteria,
Torry Research Station,
PO Box 31,
135 Abbey Road
ABERDEEN,
AB9 8DG,
Scotland

Bacteria of marine importance

National Collection of Marine Bacteria,
Torry Research Station,
PO Box 31,
135 Abbey Road,
ABERDEEN,
AB9 8DG.
Scotland.

Bacteria of medical and veterinary importance

National Collection of Type Cultures,
Central Public Health Laboratory,
Colindale Avenue,
LONDON,
NW9 5HT.

Bacteria from milk and milk products

National Collection of Dairy Organisms,
National Institute for Research in Dairying,
Shinfield,
READING,
Berkshire,
RG2 9AT.

Bacteria pathogenic for plants

National Collection of Plant Pathogenic Bacteria,
Plant Pathology Laboratory,
Hatching Green,
HARPENDEN,
Hertfordshire,
AL5 2BD.

Fungi and yeasts pathogenic for man and animals

Mycological Reference Laboratory,
London School of Hygiene and Tropical Medicine,
Keppel Street (Gower Street),
LONDON
WCIE 7HT.

Fungi, wood rotting

Building Research Establishment, Princes Risborough Laboratory,
Princes Risborough
AYLESBURY,
Buckinghamshire
HP17 9PY.

Fungi (other than animal pathogens and wood-rotting fungi)

Collection of Fungus Cultures,
Commonwealth Mycological Institute,
Ferry Lane,
KEW,
Surrey,
TW9 3AF.

Yeasts (other than pathogens)

National Collection of Yeast Cultures,
Brewing Industry Research Foundation,
Lyttel Hall,
NUTFIELD,
Near Redhill.
Surrey.
RH1 4HY.

STRAIN NUMBERS AND REFERENCES TO THE USE OF CULTURES

Specific names are, in effect, expressions of taxonomic opinion and as such liable to change: precise identification of strains can only be achieved by absolute fixity of strain number. Strain numbers will, therefore, never be altered whatever changes are made to specific names or groupings. If a strain is irreplaceably lost, its strain number will never be used again. Unfortunately, when the Göttingen collection was founded, the Cambridge strain numbers continued to be used there and later additions were independently given new numbers in the old notation. Hence, in some cases different strains have been given the same number. Where confusion is likely, the acronym CCAP should be used as a prefix to our strain numbers.

A sample survey of the literature on algae and protozoa showed that authors do not always give adequate reference to the strains used in work involving cultures. The sample used was the 1971 issues of fourteen journals taken at this establishment which publish original work on algae and protozoa. Papers dealing with fossils, larger seaweeds and organisms not so far cultured, were excluded.

Minimum adequate reference was considered to be the designation of the culture together with, where appropriate, indication of the source collection, e.g. CCAP 211/8d or Göttingen 11/6. A more complete reference would give also the name of the isolator and the date of isolation, but this information is usually available in the list published by the collection.

The survey showed that over three-quarters (153 out of 204) of the authors used cultures when this was possible. It also showed that well over half of the users (89 out of 153) gave inadequate or no reference to the cultures used. This is most unsatisfactory, especially when one considers the rigid insistence by authors and editors on proper bibliographic references.

References to specific names and a collection, e.g. "*Chlamydomonas globosa* from CCAP" are not satisfactory as there may be now, or in the future, more than one strain fitting that description. References such as "*Tetrahymena pyriformis* 'W' strain" are inadequate without mention of the source.. It has recently been shown (Borden, Whitt and Nanney, 1973) that strains of this species from different sources, but with the same designation, may differ, while differently designated strains may be identical. The cause of this confusion presumably lies in mislabelling and failure to record the origin of stocks used.

Among the advantages of using properly documented strains are:-

- (a) that the work can be repeated or compared with other work on the same strain; and
- (b) the comparison of different strains of a species or of different species of a genus enables the significance of the particular characters to be assessed.

Too often one sees a general statement about a species made from evidence derived from only one strain.

"TYPE" CULTURES

When a strain is described as 'type material', it has been directly derived from material from which the original description was made. It will usually have been deposited by the author of the taxon.

PRESERVATION

The long-term preservation of viable cultures by lyophilisation or storage under liquid nitrogen is now standard practice for many kinds of micro-organisms. The main advantages are greater stability of type, less handling and hence less risk of contamination or mislabelling and less space needed for storage.

Lyophilised cultures are easily stored and transported. Cultures frozen in liquid nitrogen seem to provide much better survival for many types, but the need to maintain extremely low temperatures imposes inevitable restrictions. Progress toward routine preservation of algae and protozoa has, until now, been slow.

A programme was started in CCAP in 1974 to develop methods suitable for our strains. Despite promising results with liquid nitrogen, it will be several years before the majority of strains are successfully preserved.

REQUESTS FOR CULTURES

All cultures in this list are available for research or teaching. Strains which may be serious pathogens are only supplied to laboratories with proper facilities for handling them. All requests should be addressed to:-

The Director,
Culture Centre of Algae and Protozoa,
Institute of Terrestrial Ecology,
36 Storey's Way,
CAMBRIDGE,
CB3 0DT.
England.

It is strongly recommended that the use for which cultures are required is stated with the order, as, for example, some strains are quite unsuitable for elementary teaching and others very difficult to grow in quantity. For research purposes, if no particular strain is required, some indication of the requirement to be fulfilled will enable us to select a suitable strain.

A month's notice is usually necessary, especially in the case of large orders for teaching material; priority is naturally given to orders received in good time. When cultures are required on a certain date, this should be clearly indicated; otherwise they will be sent as soon as they are ready.

Cultures are dispatched by First Class Mail or by Air Mail as appropriate. Special request must be made if cultures are to be sent by Air Freight.

A charge is made to cover the cost of production, packing, etc. For details, see current price sheet.

TEACHING

List of organisms recommended for teaching purposes

Orders from this list should be headed "For teaching". Only the genus should normally be specified, as every effort is made to supply the most suitable strain available.

One culture is normally sufficient for 25 students (of *Acetabularia*, a minimum of six mature caps is supplied).

CYANOPHYCEAE

Anabaena
Chroococcus
Gloeocapsa
Gloeostrichia (does not form typical colonies)
Merismopedia
Nodularia (marine)
Nostoc
Oscillatoria
Scytonema
Spirulina
Tolyphothrix

CHLOROPHYCEAE

Volvocales
Asteromonas (marine)
Carteria
Chlamydomonas (for morphology)
Chlamydomonas (mating strains, usually available)
Dunaliella (marine)
Eudorina
Gonium
Haematococcus
Pandorina
Pleodorina
Volvox

Ulotrichales
Cylindrocapsa
Microspora
Ulothrix (*Uronema*)

Chlorococcales
Ankistrodesmus
Chlorella
Chlorococcum
Coelastrum
Hydrodictyon
Pediastrum
Scenedesmus

Chaetophorales

Chaetophora
Coleochaete
Stigeoclonium

Cladophorales

Cladophora

Zygnemales

Closterium
Cosmarium
Micrasterias
Mougeotia
Spirogyra
Staurastrum
Zygnea

Oedogoniales

Bulbochaete
Oedogonium (male & female strains)

Siphonales

Acetabularia (marine)

PRASINOPHYCEAE

Platymonas (marine)
Prasinocladus (marine)
Pyramimonas (marine)

EUGLENOPHYCEAE

Astasia (colourless)
Euglena gracilis (for movement)
Euglena spirogyra (for cell structure)
Peranema (holozoic, shows
Trachelomonas flagellum well)

DINOPHYCEAE

<i>Amphidinium</i>	(marine)
<i>Exuviaella</i>	(marine)
<i>Glenodinium</i>	(marine)
<i>Gymnodinium</i>	(marine)
<i>Gymnodinium (Woloszynskia)</i>	(marine or freshwater)
<i>Oxyrrhis</i>	(marine)
<i>Peridinium</i>	(marine or freshwater)
<i>Prorocentrum</i>	(marine)

CRYPTOPHYCEAE

<i>Chilomonas</i>	(colourless)
<i>Cryptomonas</i>	(marine or freshwater)

CHrysophyceae

<i>Ochromonas</i>	(marine or freshwater)
<i>Pseudopedinella</i>	(marine)
<i>Synura</i>	

PHAEOPHYCEAE

<i>Ectocarpus</i>	(marine)
-------------------	----------

RHODOPHYCEAE

<i>Acrochaetium</i>	(marine)
<i>Chroothecete</i>	(marine)
<i>Porphyridium</i>	unicellular

SARCODINA**Amoebae:**

<i>Amoeba proteus</i>	
<i>Chaos carolinense</i>	(larger than <i>A. proteus</i> ; multinucleate)
<i>Naegleria gruberi</i>	(amoeba/flagellate transformation; encystment and excystment)
<i>Saccamoeba limax</i>	(medium sized; good for amoeboid movement & contractile vacuole)

Testate amoebae:*Arcella***Cellular slime moulds:***Dictyostelium* (aggregation, sorocarps)**XANTHOPHYCEAE**

<i>Botrydiopsis</i>	
<i>Bumilleria</i>	(larger than <i>Tribonema</i> and shows H-pieces better)
<i>Ophiocytium</i>	
<i>Tribonema</i>	
<i>Vaucheria</i>	
<i>Vaucheria</i>	(fertile, limited amount of material only)

HAPTOPHYCEAE

<i>Chrysochromulina</i>	(marine)
<i>a coccolithophorid</i>	(marine)
<i>Isochrysis</i>	(marine)

BACILLARIOPHYCEAE

<i>Coscinodiscus</i>	(marine) centric
<i>Navicula</i>	(marine) motile
<i>Nitzschia</i>	(marine) motile
<i>Phaeodactylum</i>	(marine)
<i>Pinnularia</i>	
<i>Skeletonema</i>	(marine)

CILIOPHORA

<i>Paramecium caudatum</i>	
<i>Paramecium bursaria</i>	
(for conjugation, zoochlorellae)	
<i>Tetrahymena</i>	(axenic)
<i>Coleps</i>	(with 'armour')
<i>Discophrya</i>	(suctorian)
Rotifers are also available	

<i>Stentor</i>	
<i>Spirostomum</i>	
<i>Blepharisma</i>	
<i>Neobursaridium</i>	(large)
<i>Stylonychia</i>	(hypotrich)
<i>Euplates</i>	(hypothrich; our present species are marine)

DEPOSITION OF CULTURES

Intending depositors should first apply to the Senior Officer.

We generally welcome the deposition of cultures of value whether of taxonomic, physiological or other importance, especially those that have been the subject of publication. It is recommended that important strains should be deposited in at least two major collections for safe keeping.

Depositors are requested to supply as much information as possible about their strains, preferably on our data sheets (available on request), or on World Federation of Culture Collections form SCC-4. Reprints relating to strains are most useful.

If desired, a newly-deposited culture may be withheld from issue for a limited time, usually until publication is effected.

Depositors may, within limits, receive cultures of their own strains free of charge.

Arrangements can be made for the deposition of strains, subject to patent applications.

SYSTEMATIC LIST OF GENERA OF ALGAE AND PROTOZOA IN THE COLLECTION

CHLOROPHYCEAE

Volvocales

<i>Balticola</i>	<i>Pascherina</i>
<i>Brachiomonas</i>	<i>Phacotus</i>
<i>Carteria</i>	<i>Platydorina</i>
<i>Chlamydomonas</i>	<i>Pleodorina</i>
<i>Chlorogonium</i>	<i>Polytoma</i>
<i>Dunaliella</i>	<i>Polytomella</i>
<i>Dysmorphococcus</i>	<i>Pteromonas</i>
<i>Eudorina</i>	<i>Pyrobotrys</i>
<i>Gloeomonas</i>	<i>Spermatozopsis</i>
<i>Gonium</i>	<i>Sphaerellopsis</i>
<i>Haematococcus</i>	<i>Stephanosphaera</i>
<i>Lobomonas</i>	<i>Volvox</i>
<i>Pandorina</i>	<i>Volvulina</i>

Chlorococcales

<i>Ankistrodesmus</i>	<i>Hyaloraphidium</i>
<i>Asterococcus</i>	<i>Hydrodictyon</i>
<i>Borodinella</i>	<i>Hypnomonas</i>
<i>Bracteacoccus</i>	<i>Kentrosphaera</i>
<i>Characium</i>	<i>Kirchneriella</i>
<i>Chlorella</i>	<i>Lagerheimia</i>
<i>Chlorochytrium</i>	<i>Micractinium</i>
<i>Chlorococcum</i>	<i>Muriella</i>
<i>Chlorothecium</i>	<i>Myrmecia</i>
<i>Coccomyxa</i>	<i>Nannochloris</i>
<i>Coelastrella</i>	<i>Neospongiococcum</i>
<i>Coelastrum</i>	<i>Nephrochlamys</i>
<i>Crucigenia</i>	<i>Oocystis</i>
<i>Cystococcus</i>	<i>Pediastrum</i>
<i>Dactylococcus</i>	<i>Polyedriopsis</i>
<i>Dictyococcus</i>	<i>Prototheca</i>
<i>Dictyochloris</i>	<i>Pseudochlorococcum</i>
<i>Dictyosphaerium</i>	<i>Pseudococcomyxa</i>
<i>Dimorphococcus</i>	<i>Quadrigula</i>
<i>Elakothrix</i>	<i>Radiosphaera</i>
<i>Eremosphaera</i>	<i>Rhopalocystis</i>
<i>Fusola</i>	<i>Scenedesmus</i>
<i>Glaucoctysis*</i>	<i>Scotiella</i>
<i>Golenkiniopsis</i>	<i>Selenastrum</i>
<i>Gomontia</i>	<i>Spongiochloris</i>
<i>Halochlorella</i>	<i>Tetraedron</i>
<i>Halochlorococcum</i>	<i>Trebouxia</i>
<i>Heterogonium</i>	

* Robinson and Preston (1971) suggest that *Glaucoctysis* could be:
 (1) a red alga; (2) a primitive dinoflagellate; or (3) of an independent group; but not a blue-green symbiont in a colourless green alga.

Tetrasporales

Actinochloris
Asterococcus
Chaetopeltis
Glaucosphaera
Gloeocystis

Nautococcus
Neochloris
Palmodictyon
Paulschulzia
Tetracystis

Ulotrichales

Cylindrocapsa
Interfilum
Klebsormidium (Hormidium)
Microspora
Prasiococcus
Prasiola

Pseudostichococcus
Schizomeris
Sphaeroplea
Stichococcus
Ulothrix
Uronema

Chaetophorales

Caespitella
Cephaleuros
Chaetophora
Chlorosarcinopsis
Chlorosphaera
Coleochaete
Dilabifilum
Diplosphaera
Draparnaldia
Gongrosira
Leptosira

Microthamnion
Physolinium
Pilinia
Pleurastrum
Pleurococcus
Pseudendocloniopsis
Pseudendoclonium
Pseudopleurococcus

Spirogyra
Spondylosium
Staurastrum
Zygnema
Zygnemopsis

Oedogoniales

Bulbochaete
Oedocladium

Oedogonium

Siphonales (Bryopsidales)

Acetabularia
Dérbesia

Dichotomosiphon
Protosiphon

PRASINOPHYCEAE

Asteromonas
Bipedinomonas
Halosphaera
Heteromastix
Mesostigma
Micromonas
Monomastix

Nephroelmis
Pedinomonas
Platymonas
Prasinocladus
Pyramimonas
Stephanoptera
Tetraselmis

XANTHOPHYCEAE

Botrydiopsis
Botrydium
Botryococcus
Bumilleria
Bumilleriopsis
Chlorellidium
Chloridella
Chlorocloster
Heterococcus

Heterothrix
Mischococcus
Nephrodiella
Ophiocytium
Pleurochloris
Sphaerosorus
Tribonema
Vaucheria

EUSTIGMATOPHYCEAE

Chlorobotrys
Ellipsoidion
Monodus
Pleurochloris

Polyedriella
Pseudocharaciopsis
Vischeria

CHRYSOPHYCEAE

Anthophysa
Chrysococcus
Chrysosphaera
Mallomonas
Monas
Ochromonas
Olisthodiscus

Paraphysomonas
Phaeaster
Poterioochromonas
Pseudopedinella
Spumella
Synura

HAPTOPHYCEAE

Chrysochromulina
Coccolithus
Cricosphaera
Crystallolithus
Diacronema
Dicrateria
Emiliania
Hymenomonas

Isochrysis
Monochrysis
Pavlova
Phaeocystis
Pleurochrysis
Prymnesium
Sarcinochrysis
Syracosphaera

DINOPHYCEAE

<i>Amphidinium</i>	<i>Oxyrrhis</i>
<i>Exuviaella (Prorocentrum)</i>	<i>Peridinium</i>
<i>Gloeodinium</i>	<i>Prorocentrum</i>
<i>Heterocapsa</i>	<i>Woloszynskia</i>

BACILLARIOPHYCEAE

<i>Amphiprora</i>	<i>Navicula</i>
<i>Asterionella</i>	<i>Nitzschia</i>
<i>Bacillaria</i>	<i>Pinnularia</i>
<i>Biddulphia</i>	<i>Pleurosigma</i>
<i>Chaetoceros</i>	<i>Skeletonema</i>
<i>Cyclotella</i>	<i>Stephanodiscus</i>
<i>Fragilaria</i>	<i>Tabellaria</i>
<i>Gomphonema</i>	<i>Thalassiosira</i>
<i>Melosira</i>	

CRYPTOPHYCEAE

<i>Chilomonas</i>	<i>Cyanophora</i>
<i>Chroomonas</i>	<i>Cyathomonas</i>
<i>Cryptomonas</i>	<i>Hemiselmis</i>

CHLOROMONADOPHYCEAE

<i>Fibrocapsa</i>	<i>Vacuolaria</i>
-------------------	-------------------

EUGLENOPHYCEAE

<i>Astasia</i>	<i>Khawkinnea</i>
<i>Colacium</i>	<i>Lepocinclis</i>
<i>Cryptoglena</i>	<i>Menodium</i>
<i>Cyclidiopsis</i>	<i>Parmidium</i>
<i>Distigma</i>	<i>Peranema</i>
<i>Entosiphon</i>	<i>Phacus</i>
<i>Euglena</i>	<i>Rhabdomonas</i>
<i>Eutreptia</i>	<i>Rhabdospira</i>
<i>Eutreptiella</i>	<i>Strombomonas</i>
<i>Gyropaigne</i>	<i>Trachelomonas</i>
<i>Hyalophacus</i>	

PHAEOPHYCEAE

<i>Ectocarpus</i>	<i>Streblonema</i>
-------------------	--------------------

RHODOPHYCEAE

<i>Asterocytis</i>	<i>Hildenbrandia</i>
<i>Chantransia</i>	<i>Porphyra</i>
<i>Chroothecce</i>	<i>Porphyridium</i>
<i>Cyanidium**</i>	<i>Rhodella</i>
<i>Glaucocystis*</i>	

** This alga, which at first glance is a 'blue-green Chlorella', has been placed in various other classes

* see footnote on page 9

MYXOPHYCEAE (= Cyanophyceae)

<i>Anabaena</i>	<i>Lyngbya</i>
<i>Anabaenopsis</i>	<i>Mastigocladius</i>
<i>Anacystis</i>	<i>Merismopedia</i>
<i>Aphanizomenon</i>	<i>Microchaete</i>

CULTURE MEDIA

Media may be designed for maintenance, i.e., giving prolonged survival between subculturing, for maximum growth rate, for inducing sexuality, or other special purposes. They may be chemically defined or loosely defined, i.e. containing imprecise ingredients such as soil or extracts of yeast, meat, etc. When cultures have other micro-organisms such as bacteria present, the medium must not be such as to encourage excess growth of contaminants lest they overwhelm the desired organism. In general, media with a total of 0.1 per cent or more organic nutrient are only suitable for axenic cultures.

Large numbers of cultures are maintained on the same medium mainly for convenience. It must not be assumed that one medium is optimal for many strains. Frequently, related species, or even strains within a single species, have significantly different requirements.

Details of some of our more useful maintenance media are given below. Many special media and methods for algae are given by Stein (1973) and Venkataraman (1969).

Proteose peptone (Difco)	0.1%
KNO ₃	0.02%
K ₂ HPO ₄	0.002%
MgSO ₄ .7H ₂ O	0.002%
Agar	1.0%

This medium proves satisfactory for many algae and also quickly reveals the presence of many common contaminants. For agar cultures with bacteria, a less rich medium is necessary; we generally use soil extract agar (e + s).

Soil extract stock solution	10% by volume
KNO ₃	0.02%
K ₂ HPO ₄	0.002%
MgSO ₄ .7H ₂ O	0.002%
Agar	1.0%

The soil extract stock solution is made by heating in a steamer a calcareous garden loam with twice its volume of supernatant water.

It is convenient to make up and sterilise a number of small containers of stock solution each of a size appropriate to making a batch of media. Repeated autoclaving is deleterious; excessive bacterial growth would spoil the stock solution.

Soil and water media

In spite of possible initial difficulties over selection of suitable ingredients, these media have great advantages for many purposes so long as axenic culture is not required. A well-chosen soil and water medium produces a morphologically excellent growth of almost any organism apart perhaps from the more exacting planktonic forms. The soil

* Unless otherwise indicated % means g per 100 ml.

provides not only mineral nutrients and trace elements, but the latter are naturally chelated, pH is buffered, and toxic products rendered innocuous. The microbial flora ensures a supply of growth substances.

Our basic medium "E" is made as follows:-

Put a layer about 1 cm deep of good calcareous garden loam into a test tube or jar. Carefully add 7 to 10 cm of water, plug or cover, and steam for one hour (longer for larger vessels) on each of two consecutive days. Allow to stand a further day before inoculating, when the pH should be between 7 and 8. The use of mud from rivers or ponds is seldom as satisfactory as garden soil.

Innumerable variations of this basic medium are possible. Among those we find useful are "M" in which the garden soil is replaced by a calcareous clay. The addition of a speck (say about 3% of the volume of the soil) of calcium carbonate or of ammonium magnesium phosphate beneath the soil is recommended, the former for many eutrophic Chlorophyceae, the latter for many green euglenids. Sphagnum peat may be added or may replace the soil when growing forms from acid habitats. The addition of a little starch below the soil stimulates growth of many saprophytes like *Polytoma* and *Astasia*. A pearl barley grain, rice grain or wheat grain produces a bacterial flora which forms a suitable food for many ciliates. By giving consideration to the nutrition of the organism and the nature of its habitat, one can produce soil and water media to suit many different organisms.

When selecting soils, the best method is to take a fair-sized sample, say about one cubic foot, pass this through a sieve of about 1 cm mesh and then make up media and test them with a range of organisms. Should a sample prove satisfactory, you have a sufficient stock, it being often difficult to collect an identical sample even from the same locality.

It is strongly recommended that, where possible, teachers obtain inocula from the collection well in advance and grow them in their own laboratory, using the soil and water method described above. This has the advantage of introducing the students to a culture method based on ecological principles, and with a little practice the material will be in perfect condition. With many algae, e.g. *Euglena*, *Oedogonium* and *Ochromonas*, the cell contents often become obscured by accumulated food reserves in old cultures. In other forms, e.g. *Trachelomonas* and *Pithophora*, certain morphological features only become apparent in older cultures.

Bold's basal medium, (Bischoff and Bold, 1963), is a very useful mineral medium for a wide range of algae including those from more or less eutrophic waters or from soils. It may also be supplemented by soil extract and/or vitamins.

Six stock solutions 400 ml in volume are employed, each containing one of the following salts in the concentration listed:-

NaNO ₃	10.0g
CaCl ₂ .2H ₂ O	1.0g
MgSO ₄ .7H ₂ O	3.0g
K ₂ HPO ₄	3.0g
KH ₂ PO ₄	7.0g
NaCl	1.0g

To 940 ml of distilled water are added 10 ml of each stock solution and 1.0 ml of each of the four stock trace-element solutions prepared as follows:-

- 1. 50 g EDTA and 31 g KOH dissolved in 1 litre H₂O.
2. 4.98 g FeSO₄.7H₂O dissolved in 1 litre acidified H₂O.
(Acidified H₂O: 1.0 ml H₂SO₄ added to 999 ml distilled water.)
3. 11.42 g H₃BO₃ dissolved in 1 litre H₂O.
4. The following, in amounts indicated, all dissolved in 1 litre H₂O: ZnSO₄.7H₂O, 8.82 g; MnCl₂·4H₂O, 1.44 g; MoO₃, 0.71 g; CuSO₄.5H₂O, 1.57 g; Co(NO₃)₂·6H₂O, 0.49 g.

Chu (1942) devised a series of media based on the composition of various natural waters. Chu 10, variously modified, has been used for a wide range of green and blue-green algae and also diatoms, particularly from oligotrophic or less rich eutrophic habitats.

The following is given by Gerloff, Fitzgerald and Skoog (1950).

Ca(NO ₃) ₂	0.004%
K ₂ HPO ₄	0.001%
MgSO ₄ .7H ₂ O	0.0025%
Na ₂ CO ₃	0.002%
Na ₂ SiO ₃	0.0025%
Ferric citrate	0.0003%
Citric acid	0.0003%

Nowadays, the last two ingredients are usually replaced by an iron/EDTA complex, and other trace elements and vitamins may be added as in this modification from the Windermere Laboratory of the Freshwater Biological Association.

Modified Chu 10 (EVT)

	amounts per litre
Ca(NO ₃) ₂ .4H ₂ O	20.0 mg
KH ₂ PO ₄	6.2 mg
MgSO ₄ .7H ₂ O	25.0 mg
Na ₂ CO ₃	20.0 mg
Na ₂ SiO ₃	25.0 mg
N.HCl	0.25 ml
Added as	
complex	{ EDTA.Na ₂
EDTA.Fe	{ FeCl ₃
	2.0 mg
	1.0 mg
	{ H ₃ BO ₃
	{ MnCl ₂ .4H ₂ O
	{ (NH ₄) ₆ Mo ₇ O ₂₄ .4H ₂ O
	2.48 mg
	1.39 mg
	1.00 mg
	{ vitamin B ₁₂
	{ vitamin B ₁
	{ biotin
	0.25 mg
	1.00 mg
	1.00 mg

Many strains require more specialized media; some of the most important are these:-

Euglena gracilis medium (E.g.)

Na acetate. hydrate	0.1%
Beef extract	0.1%
Yeast extract	0.2%
Bacto tryptone	0.2%
CaCl ₂	0.001%
Agar (optional)	1.0%

Ochromonas medium (Ochr)

Liver infusion (dehydrated) Oxoid	0.1%
Glucose	0.1%
Bacto tryptone	0.1%

Tetrahymena medium (P.Y.)

Proteose peptone	1.0%
Yeast extract	0.25%

Polytoma medium (Polyt.)

Na acetate. hydrate	0.2%
Yeast extract	0.1%
Bacto tryptone	0.1%
Agar (optional)	1.0%

Acanthamoeba, when axenic, is maintained in 4 per cent mycological peptone (M.P.).

Marine algae

Many marine algae thrive in Erdschreiber medium:-

Natural seawater	1 litre
Soil extract stock solution	50 ml
NaNO ₃	0.2 g
Na ₂ HPO ₄ .12H ₂ O	0.03 g

The seawater is filtered, pasteurized, and added to the other ingredients after they have been autoclaved.

For more exacting marine algae, media such as ASP2 (Provasoli et al, 1957) are used, often mixed with an equal part of Erdschreiber. Organisms from polluted marine or estuarine habitats often thrive in a soil and water medium made with an appropriate concentration of seawater.

The following are only two of many liquid media used for *Chlorella*, *Chlamydomonas* and other green algae.

Chlorella, Sorokin and Krauss (1958)

(g/litre)

KNO ₃	1.25
KH ₂ PO ₄	1.25
MgSO ₄ .7H ₂ O	1.00
CaCl ₂	0.0835
H ₃ BO ₃	0.1142
FeSO ₄ .7H ₂ O	0.0498
ZnSO ₄ .7H ₂ O	0.0882
MnCl ₂ .4H ₂ O	0.0144
MoO ₃	0.0071
CuSO ₄ .5H ₂ O	0.0157
Co(NO ₃) ₂ .6H ₂ O	0.0049
EDTA	0.5

Chlamydomonas reinhardtii

For genetic studies, this alga has been grown in the following medium by Sueoka (1960) and Levine's group at Harvard:-

	Minimal medium
* NH ₄ Cl	0.05 g
MgSO ₄ .7H ₂ O	0.02 g
CaCl ₂ .2H ₂ O	0.01 g
** K ₂ HPO ₄	0.72 g
** KH ₂ PO ₄	0.36 g
Hutner's trace elements	1 ml
Distilled water	1 litre

Hutner's trace elements solution: (g)

EDTA	50.0
ZnSO ₄ .7H ₂ O	22.0
H ₃ BO ₃	11.4
MnCl ₂ .4H ₂ O	5.1
FeSO ₄ .7H ₂ O	5.0
CoCl ₂ .6H ₂ O	1.6
CuSO ₄ .5H ₂ O	1.6
(NH ₄) ₆ Mo ₇ O ₂₄ .4H ₂ O	1.1
Distilled water (ml)	750

Boil, cool slightly, and bring to pH 6.5 - 6.8 with KOH (do not use NaOH). The clear solution is diluted to 1000 ml with distilled water and should have a green colour which changes to purple on standing. It is stable for at least one year.

For heterotrophic acetate mutants, the medium may be supplemented with sodium acetate at a concentration in the medium of 0.2%.

- * concentration may be increased 10-fold
- ** concentration may be doubled

Blue-green algae

Medium C of Kratz and Myers (1955) is a favourite medium used by investigators working with "Anacystis nidulans" or other blue-green algae.

	(g/litre)
MgSO ₄ .7H ₂ O	0.25
K ₂ HPO ₄	1.00
Ca(NO ₃) ₂ .4H ₂ O	0.025
KNO ₃	1.0
Na ₃ citrate.2H ₂ O	0.165
Fe ₂ (SO ₄) ₃ .6H ₂ O	0.004
A ₅ microelements	1.0 ml

Microelements stock solution:

H ₃ BO ₃	2.86
MnCl ₂ .4H ₂ O	1.81
ZnSO ₄ .7H ₂ O	0.222
MoO ₃ (85%)	0.0177
CuSO ₄ .5H ₂ O	0.079

Several other media for blue-green algae are given by Carr and Whitton (1973, Appendix B).

Media for protozoa

Free-living protozoa, apart from the phytoflagellates are nearly all facultative or obligate phagotrophs. Only a few forms such as *Tetrahymena* and *Acanthamoeba* thrive in axenic liquid culture. Most protozoa grow best in agnotoxic culture with bacteria and perhaps other micro-organisms as food. In some cases, they can be grown in monoxenic culture with one known food organism.

Free swimming ciliates such as *Paramecium* and *Spirostomum* thrive in soil and water medium (see page 15) with the addition of a barley grain or other source of nutrient to provide a flourishing bacterial flora as food for the ciliate. Other protozoa may be more exacting and, in any case, sessile or bottom-living forms may be difficult to separate from the soil particles. Details of media are available on request.

A simple method for the cultivation of *Amoeba proteus*

This method, not original with us, has proved very satisfactory for the easy maintenance of cultures for teaching purposes, assuming that the inoculum includes not only *Amoeba proteus*, but also a food organism (e.g. *Chilomonas paramecium*).

Pour Prescott's and James's solution (see below) into a dish such as a crystalizing dish (diameter ca. 100 mm or a little smaller) to a depth of approximately 1 cm. Add 3 or 4 uncooked rice grains, and then inoculate with 1 or 2 ml of healthy culture of *Amoeba proteus* containing the food organisms. (If you intend to propagate the culture which you obtain from us, request a culture already containing *Chilomonas*, since we also supply from mass cultures not containing *Chilomonas*.) Cover with half a petri dish or other loose cover, and keep preferably at a temperature of 18 or 19°.

In six or eight weeks, the culture should contain good numbers of amoebae, including some among the fungal mycelia usually growing out from the rice grains, and should still be usable after three months. In a health culture, amoebae are moving with pseudopodia well extended. When most amoebae consist of only monopodial elongated forms, the culture is no longer in very good condition, and rounded cells are also usually unhealthy. Be sure to distinguish between amoebae and elongated bits of detritus.

Amoeba proteus seems to need a few bacteria, so sterilisation of the medium is not recommended. Subculture every two months.

Prescott's and James's solution

Make up three stock solutions:

A	CaCl ₂	0.327 g
	KCl	0.162 g
	Distilled water to 100 ml	
B	K ₂ HPO ₄	0.512 g
	Distilled water to 100 ml	
C	MgSO ₄ .7H ₂ O	0.280 g
	Distilled water to 100 ml	

Final solution: 1 ml each of A, B, and C in 997 ml distilled water.

If you cannot prepare the Prescott's and James's solution, try filtered and boiled water from a fairly clean pond or stream.

LIST OF ALGAE AND PROTOZOA

ACANTHAMOEBA Volkonsky

A. astronyxis (Ray *et* Hayes)

LB 1534/1 Harrison 1957: material from Ray: Washington USA

CHLORELLA Beijerinck

It has long been recognised that the specific names given to strains of *Chlorella* have in many cases been useless or even misleading. The names *C. pyrenoidosa* and *C. vulgaris* especially have been used with little regard for either the characters of the alga or the code and practice of nomenclature. In general, we follow the revision of Fott and Novakova (1969) as modified by Kessler (1974) and confirmed by Morris (1976). Unfortunately, over the years, there has been some confusion of strains in all the main culture collections. Where the Göttingen strains have proved different from ours of the same designation, we have distinguished them by adding 'Gö' or 'CCAP' to the strain number.

All except the marine strains are now preserved under liquid nitrogen, indicated by 'N'. Only the strains in frequent demand will still be maintained on agar slopes. The marine species have not yet been taxonomically revised.

Chlorella autotrophica Shihira et Krauss

=*C. vulgaris* var. *autotrophica* (S. et K.) Fott et Novakova

C. candida S. et K.

=*C. vulgaris* var. *vulgaris* according to F. et N.

C. ellipsoidea Gerneck

=*C. saccharophila* var. *ellipsoidea* (Gerneck) F. et N.

C. emersonii S. et K. var. *emersonii* (formerly *C. fusca* var. *vacuolata*.

see Fott et al., 1975)

N	211/8a	Pringsheim: type material of <i>C. photophila</i> S. et K.

CHLORELLIDIUM Vischer *et* Pascher

C. tetrabotrys Vischer *et* Pascher

811/1a Vischer No. 153: Switzerland
811/1b Vischer No. 155: Czechoslovakia

CHLORHORMIDIUM Fott = *Klebsormidium* Silva, Mattox *et* Blackwell

CHLORIDELLA Pascher

C. minuta Moewus
813/2 Moewus: type material

C. neglecta Pascher
813/1 Vischer 1940, No. 216: from soil: Switzerland

CHLOROBOTRYS Bohlin

C. regularis (W. West) Bohlin
LB 810/1 Hibberd 1967: England

CHLOROCYTRIDION Vischer

C. tuberculata Vischer see *Pedinomonas tuberculata*

CHLOROCYTRIUM Cohn

C. spp.
212/1 Mitra/Pringsheim
LB 212/2 George 1952: England

CHLOROCLOSTER Pascher

C. engadinensis Vischer
812/1 Vischer 1940, No. 252: from soil: Switzerland

C. solani George see *Pseudococcomyxa adhaerens*

Our strains of *Chlorocloster* were shown to contain chlorophyll b. They are presumably not therefore members of the Xanthophyceae. Until the type species is checked, *Chlorocloster* may itself still be a xanthophycean genus.

CHLOROCOCCUM Meneghini

C. echinozygotum Starr
213/5 Bold: type material: from soil: Philippine Is.

C. hypnosporum Starr
213/6 Bold: type material: from soil: Tennessee USA
237/1 Pringsheim 1940: formerly listed as *Hypnomonas lobata*
Korsh: soil: England

C. infusionum (Schrank) Meneghini
 213/2a Mainx
 213/2b Mainx

C. macrostigmatum Starr
 213/9 Starr: from soil: Connecticut USA

C. minutum Starr
 213/7 Bold: type material: from soil: India

C. multinucleatum Starr = *Neospongiococcum granatum* Deason
 213/1a Pringsheim (as *C. humicolum*): type material: from soil

C. vacuolatum Starr
 213/8 Starr 1952: type material: from soil: South Africa

C. wimmeri Rabenhorst = *Neochloris wimmeri* (Rab.) Archibald et Bold
 213/4 Mainx: Meyer No. Chlor. 7

CHLOROGLOEA Wille

C. fritschii Mitra (= ? *Nostoc* sp.)
 LB 1411/1a Mitra 1950: No. 7: type material: from soil: India

C. sp.
 L 1411/2 Kunisawa, Stanier 6712: California USA

CHLOROGLOEOPSIS Mitra et Panday

C. sp. "Chlorogloea fritschii"
 1411/1b origin previous to Botany Department, Berkeley, is
 uncertain: Stanier 6718: fixes nitrogen

CHLOROGONIUM Ehrenberg

C. elongatum Dangeard
 12/1 Pringsheim 1942: England
 12/2a Hartmann/Pringsheim
 12/2b George 1948: South Africa
 12/2c Pringsheim 1949: France
 12/2d Pringsheim 1951: South Africa
 12/4 Meyer: formerly listed as *C. tetragamum*:
 Czechoslovakia

C. euchlorum Ehrenberg
 12/3 Kniep/Mainx: Germany

C. spp.
 LB 12/5 Pringsheim as K
 L 12/6 Pringsheim as N

CHLOROMESON Pascher

C. sp.
 LB 814/1 Butcher 1954: marine: England

CHLOROSARCINOPSIS Herndon

C. negevensis Friedmann et Ocampo-Paus *f. ferruginea*
14/1 Baldinger 1-112: type material: Negev Desert

C. negevensis *f. negevensis*
14/2 Baldinger 1-116: type material: Negev Desert

C. semperfiriens Groover et Bold
214/1 Pringsheim: type material, probably isolated in Prague before 1939
