# Hydrological Summary for the United Kingdom 

#### Abstract

General April was a generally mild and unsettled month but, north-western Britain aside, rainfall deficiencies increased in most areas broadening the drought's impact but also reinforcing its regional focus. For England \& Wales, rainfall over the 18 months to April is the second lowest since 1975/76 but deficiencies over parts of central and southern England are the greatest since 1932-34. Overall reservoir stocks for E\&W are marginally above average and very similar to early May 2005. Aided by drought mitigation measures (e.g. at Bewl Water), reservoir levels are generally healthy apart from a few southern impoundments (e.g. Weir Wood, Colliford). Modest spates in many responsive southern catchments helped raise April runoff totals well above drought minima but flows are very meagre in many spring-fed streams. Correspondingly, groundwater levels are very depressed in parts of the English Lowlands, albeit mostly above corresponding levels recorded during in the protracted droughts of the 1990s. In much of central and southern England, increasing evaporation rates and soil moisture deficits in early May very probably signal the end of the 2005/06 recharge season. Groundwater levels and river flows are set to decline through the summer with the prospect of exceptionally low flows by the autumn.

## Rainfall

Westerly airflows predominated during April bringing abundant rainfall to western Scotland but most low pressure systems weakened crossing the UK. Some catchments in Kent and Sussex benefited from seasonally late snow (up to 15 cm in places on the 10th) but light showers and drizzle were the primary precipitation types in eastern and southern Britain; the only sustained frontal rainfall in parts of the South being registered on the $30^{\text {th }}$. Reflecting a recurring pattern in the recent past, northwestern Britain was notably wet - parts of the western Highlands reporting twice the average April rainfall. By contrast, much of southern England registered well below average totals with many catchments in the South West registering $<50 \%$. Much of north-eastern Britain was also notably dry - some localities in Fife reporting monthly totals of only around 5 mm . Rainfall for E\&W over the Nov-April period for both 2004/05 and 2005/06 ranks amongst the lowest five in the last 50 years. More significantly, the 2-year winter/spring deficiencies for the Thames catchment are, provisionally, the lowest since 1890-92. Rainfall deficiencies since October 2004 are the equivalent of $4-5$ months average rainfall over much of southern and central England but local variations in drought severity are significant; parts of London, east Kent, the Test basin (Hampshire) and south Dorset constitute pockets of particular intensity.

## Flows

April river flow patterns were characterised by steep recessions in most index rivers across the UK. However for a few of the most drought-affected rivers (including the Medway and Sussex Ouse), April runoff was close to average; a valuable recovery at a critical time. More generally in southern England minor spates in responsive catchments helped maintain flows above drought minima. April runoff totals testify to an exaggeration in the normal NW/SE runoff gradient across the UK. Whilst the River Naver registered its highest April mean flow in a 30-year series, flows in some lowland spring-fed rivers in the South East were among the lowest on record. Nonetheless, April runoff for most index rivers was in the normal range. This contrasts with runoff accumulations over the winter and early spring and, more significantly, over the last 18
months; these confirm the drought's focus on southern Britain. Index rivers establishing new 18 -month (ending in April) runoff minima include the Kenwyn, Medway and Test; flows in the latter have been below average for $>30$ months and the April runoff was the $2^{\text {nd }}$ lowest (after 1976) on record. Flows in many Chalk streams are already well below those of a typical late summer and set to decline further - with a substantial contraction in the stream network, associated habitat loss and an increasing risk of algal blooms and other water quality problems.

## Groundwater

April was a further month with below average, and spatially very variable, rainfall across most of the main aquifer outcrop areas. In a few areas, late-season recharge substantially improved the groundwater outlook (e.g. in parts of Sussex and Kent). But generally, April's patchy rainfall produced very limited infiltration in most of the drought affected region where, after two of the least productive winter/spring recharge seasons in the modern era, the 2006 groundwater level recessions will begin from well below normal spring maxima. The health of groundwater resources currently displays large regional and more local variations but groundwater levels are generally less depressed than at the same time in 1997 or 1992. However, previous late spring minima in the Chalk have been eclipsed in parts of the North Downs and the Chilterns. On the Isle of Wight, levels in the Greensand (at Alverstone) are also at their lowest on record for April. Recharge to the limestone aquifers was erratic over the winter but moderate spring recoveries have generally left levels in index boreholes well within the normal range. Outcrops of the Permo-Triassic sandstones present a much less spatially coherent picture but with exceptionally low levels in many Midland index wells. Morris Dancers is at its lowest April level in a 37-year record, Weeford Flats is dry, and levels at Heathlanes are approaching late spring minima. Levels are also depressed in some eastern minor aquifers (e.g.Woburn Sands and Suffolk Crag). The incidence of spring failures and wells drying-up will increase as summer groundwater level recessions develop - these are likely to be relatively gentle as natural base levels are approached.

\% = percentage of 1961-90 average $\quad R P=$ Return period
The monthly rainfall figures* provided by the Met Office (National Climate Information Centre) are Crown Copyright and may not be passed on to, or published by, any unauthorised person or organisation. All monthly totals since November 2005 are provisional (see page 12). 1961-2003 regional monthly totals were revised by the Met Office in 2004. Most of the return period estimates are based on tables provided by the Met Office (see Tabony, R. C., 1977, The variability of long duration rainfall over Great Britain, Scientific Paper No. 37) and relate to the specified span of months only (return periods may be up to an order of magnitude less if n-month periods beginning in any month are considered); RP estimates for Northern Ireland are based on the tables for north-west England. The tables reflect rainfall over the period 1911-70 and assume a stable climate. Artifacts, in the Scottish rainfall series in particular, can exaggerate the relative wetness of the recent past. ${ }^{*}$ See page 12.

## Rainfall . . . Rainfall

Key
Sery Normal range

November 2005 - April 2006

## Rainfall accumulation maps

Rainfall over the six months to April 2006 was considerably below average in almost all regions and the UK registered its 2nd lowest rainfall, in this timeframe, since 1975/76. The greatest deficiencies were across the English Lowlands and their significance is underlined by the map of 18-month rainfall percentages which confirms that large parts of southern England are experiencing long term deficiencies - the drought's severity reflects the disproportionate contribution of the winter months to this overall deficiency.

## River flow . . . River flow

## River flows

*Comparisons based on percentage flows alone can be misleading. A given percentage flow can represent extreme drought conditions in permeable catchments where flow patterns are relatively stable but be well within the normal range in impermeable catchments where the natural variation in flows is much greater. Note: the period of record on which these percentages are based varies from station to station. Percentages may be omitted where flows are under review.

## River flow . . . River flow

## River flow hydrographs

The river flow hydrographs show the daily mean flows together with the maximum and minimum daily flows prior to May 2005 (shown by the shaded areas). Daily flows falling outside the maximum/minimum range are indicated where the bold trace enters the shaded areas.

## Groundwater . . . Groundwater

Groundwater levels normally rise and fall with the seasons, reaching a peak in the spring following replenishment through the winter (when evaporation losses are low and soil moist). They decline through the summer and early autumn. This seasonal variation is much reduced when the aquifer is confined below overlying impermeable strata. The monthly mean and the highest and lowest levels recorded for each month are displayed in a similar style to the river flow hydrographs. Note that most groundwater levels are not measured continuously - the latest recorded levels are listed overleaf.

## Groundwater . . .Groundwater

## Groundwater levels - April 2006

The rankings are based on a comparison between the average level in the featured month (but often only single readings are available) and the average level in each corresponding month on record. They need to be interpreted with caution especially when groundwater levels are changing rapidly or when comparing wells with very different periods of record. Rankings may be omitted where they are considered misleading.
Notes: i. The outcrop areas are coloured according to British Geological Survey conventions.
ii. Yew Tree Farm levels are now received quarterly.

# National Hydrological Monitoring Programme 

The National Hydrological Monitoring Programme (NHMP) was instigated in 1988 and is undertaken jointly by the Centre for Ecology and Hydrology Wallingford (formerly the Institute of Hydrology - IH) and the British Geological Survey (BGS). Financial support for the production of the monthly Hydrological Summaries is provided by the Department for Environment, Food and Rural Affairs (Defra), the Environment Agency (EA), the Scottish Environment Protection Agency (SEPA), the Rivers Agency (RA) in Northern Ireland, and the Office of Water Services (OFWAT).

## Data Sources

River flow and groundwater level data are provided by the Environment Agency, the Environment Agency Wales, the Scottish Environment Protection Agency and, for Northern Ireland, the Rivers Agency and the Department of the Environment (NI). In all cases the data are subject to revision following validation (flood and drought data in particular may be subject to significant revision).

Reservoir level information is provided by the Water Service Companies, the EA, Scottish Water and the Northern Ireland Water Service.

The National River Flow Archive (maintained by CEH Wallingford) and the National Groundwater Level Archive (maintained by BGS) provide the historical perspective within which to examine contemporary hydrological conditions.

## Rainfall

Most rainfall data are provided by the Met Office (see opposite). To allow better spatial differentiation the rainfall data for Britain are presented for the regional divisions of the precursor organisations of the EA and SEPA. Following the discontinuation of the Met Office's CARP system in July 1998, the areal rainfall figures have been derived using several procedures, including initial estimates based on MORECS*. Recent figures have been produced by the Met Office, National Climate Information Centre (NCIC), using a technique similar to CARP. A significant number of additional monthly raingauge totals are provided by the EA and SEPA to help derive the contemporary regional rainfalls. Revised monthly national and regional rainfall totals for the post-1960 period (together with revised 1961-90 averages) were made available by the Met Office in 2004; these have been adopted by the NHMP. As with all regional figures based on limited raingauge networks the monthly tables and accumulations (and the return periods associated with them) should be regarded as a guide only.
*MORECS is the generic name for the Met Office services involving the routine calculation of evaporation and soil moisture throughout Great Britain.

The National Hydrological Monitoring Programme depends on the active cooperation of many data suppliers. This cooperation is gratefully acknowledged.

## Subscription

Subscription to the Hydrological Summaries costs $£ 48$ per year. Orders should be addressed to:

[^0]:    Details of the individual reservoirs in each of the groupings listed above are available on request. The featured reservoirs may not be representative of the storage conditions across each region; this can be particularly important during droughts. The storage figures relate to the 1988-2006 period only (except for West of Scotland and Northern Ireland where data commence in the mid-1990's). In some gravity-fed reservoirs (e.g. Clywedog) stocks are kept below capacity during the winter to provide scope for flood attenuation purposes.
