TITLE	
SeaSoar and CTD sections across the Iceland-Faeroes Front and Faeroe Shetland Channel, August 1990.	
REFERENCE	
Institute of Oceanographic Sciences Deacon Laboratory, Report , No. 295, 124pp.	
ABSTRACT	
<p>In August 1990, RRS <i>Charles Darwin</i> Cruise 51 made two CTD and four SeaSoar sections across the inflow to the GIN Seas in addition to one large scale SeaSoar survey of the Iceland-Faeroes Front, and three repeat fine scale SeaSoar surveys of a selected region of the Front.</p> <p>Sections of temperature, salinity and derived parameters including sound speed are presented. The data provide detailed information to identify water mass characteristics and indicate their relative locations. In addition, the SeaSoar surveys of the Iceland-Faeroes Front present a time sequence in which the generation and development of meanders and eddies may be observed.</p>

INTRODUCTION

RRS Charles Darwin Cruise 51 took place between the 24th of July and the 20th of August 1990 (Griffiths 1990). The cruise track (Figure 1) encompassed the Iceland Færöes Front and the inflow to the Norwegian Sea. Five towed SeaSoar surveys were carried out and 18 full ocean depth CTD stations were sampled.

The first CTD section, comprising 9 stations began at 17:12 hrs on the 25th of July. With the exception of one station the CTD section was entirely successful, however on station 5105 the CTD/bottle rosette frame touched the bottom resulting in the destruction of three 10 litre Niskin bottles, but luckily no damage to either the CTD or the frame.

Having completed the first CTD section at 13:55 hrs on the 26th of July the first of the SeaSoar surveys began at 18:50 hrs on the same day and, lasting four days, established the extent of North Atlantic Water in the region north east of the Færöe Islands. Very early in this survey it became apparent that intense seasonal heating and low wind mixing of the upper 20m of the water column would result in little surface expression of a front being found virtually throughout the cruise. After completion of a further 9 station CTD section (Figure 1) SeaSoar was redeployed at 22:30 hrs on the 31st of July to begin the large scale survey of the Iceland Færöes Front. This survey took until the 8th of August to complete with only one short break when hydraulic control of SeaSoar was lost due to a cable termination failure. These data have been used to describe the water masses and mixing between Iceland and Scotland (Read and Pollard 1992).

The large scale survey made eight crossings of the IFF in 200 km legs running SSW-NNE (and vice-versa) approximately 40 km apart and clearly indicated the presence of a northward intrusion of Atlantic water to a depth of 300m centred at around 10°W. It was therefore decided that the repeated fine scale surveys, surveys 3 and 4, should cover the warm intrusion identified in the large scale survey and particularly the associated smaller scale eddies and meanders that were only partially resolved at the larger scale. The fine scale surveys had legs of around 80 km in length, 15 km apart, running in a parallel direction to those of the large scale survey (Figures 2 and 3); this track length was fixed for the SeaSoar towing speed (8 knots) in an attempt to synchronise with the M₂ tidal cycle. The first of the fine scale surveys began at 18:30 hrs on the 9th of August and ended in the early afternoon of the 12th of August. Just prior to recovery the strain gauge connected to the SeaSoar towing cable read full - scale, indicating dangerously high cable tension; however as the weather was calm and SeaSoar was due to be recovered in a few hours the survey was continued to its planned completion with a close vigil being kept on vehicle depth and behaviour. SeaSoar was deployed again just before midnight on the 12th of August for the second fine scale survey, a repeat of the first, which was completed just a little under

three days later on the 15th. Small scale features identified in the large scale survey were clearly observed and their changing geographical position monitored in the fine scale surveys. With spare time available after successful mooring and drifter recoveries, it was considered worthwhile to redeploy SeaSoar a final time at the north east corner of the fine scale survey box in the evening of the 16th of August and make a third fine scale survey (Figure 4). This last survey was shorter than the previous two and finished at 16:50 hrs on the 18th of August at which time SeaSoar was recovered and the ship set course for Troon.

SEASOAR DATA

The IOSDL SeaSoar vehicle body, containing shallow CTD 01 and an RVS loaned Chelsea Instruments fluorimeter, was used for all the SeaSoar surveys on CD51. This totalled 425.5 hrs and 6350 km of towing with SeaSoar undulating between the surface and 410m, where the bathymetry allowed, at a ship speed of 8 knots (Griffiths 1990).

The first order processing of SeaSoar data was completed at sea in four hour segments and involved the removal of spikes and the correction of obvious large shifts in computed salinity values. To facilitate this, at the end of every four hour watch, the data were plotted as temperature vs. pressure, salinity vs. pressure, fluorescence vs. pressure, temperature vs. salinity and temperature, salinity, fluorescence and pressure vs. time. Up and down profiles were colour coded and successive groups of four profiles were offset from each previous group. Two different plotting scales were necessary for the TvsP plots to enable individual profile identification in all water masses. Generally temperature, pressure and fluorimeter data were relatively clean and only required the occasional removal of spikes particularly a number of spikes to extreme minimum temperature and maximum salinity. Conductivity cell fouling caused offsets to appear in the computed salinity data values which could be identified as deviations in the usually stable T-S relationship at the deeper levels. Many such offsets were corrected on board to bring values back to the expected T-S line. Generally fouling affected only a part of an up and down cycle since the turbulent environment near the sea surface cleared the cell. However some fouling was so heavy that parts of the trace had to be discarded and offsets could only be partially resolved and corrected in the time available at sea.

After each four hourly editing session the cleaned up data were appended into sixteen hour sections, each overlapping its antecedent by four hours. These sections were merged with navigation data and the sawtooth profile of pressure with distance travelled, inherent in SeaSoar data (Griffiths 1990, Pollard 1986), was averaged to create 4 km along track by 8 m depth and 0.02 kgm⁻³ density grids. Whilst the cruise proceeded the gridded files were plotted as computer contoured sections similar to those presented in this report, for temperature, salinity and density.

Navigation data were obtained throughout the cruise using the GPS network of satellites. The GPS accuracy had been downgraded for commercial use just prior to CD51, however whilst the ship was docked at Aberdeen before the cruise position fixes were taken every 5 seconds for a period of over 15 hours to estimate the implication of this degradation (Griffiths 1990). The conclusion reached was that to achieve an accuracy of 1cms^{-1} in the ship's velocity an average derived from GPS over 12 minutes had to be made. Armed with this information navigation data were obtained to very high standard throughout the cruise. In addition, whilst a minimum of two satellites are required to make a position fix, accuracy was further enhanced by the availability of three or more satellites for 94% of fixes to begin with increasing to 100% of fixes later in the cruise.

SEASOAR SENSOR CALIBRATION

Pressure

The calibration for pressure was determined by laboratory measurements :-

$$P_1 = (P_{\text{raw}} * 0.01) * 1.000385 - 0.577$$

Temperature

The platinum resistance thermometer in shallow CTD 01 was also calibrated in the laboratory:

$$T = (T_{\text{raw}} * 0.0005) * 0.9990762 - 0.09374233$$

where raw temperature was calculated using a time constant (deltat) of 0.22 to compensate for the different response times of the temperature and conductivity sensors.

Conductivity

Bottle salinity samples were taken at one hour intervals throughout each SeaSoar survey from the ship's non-toxic seawater supply and analysed in the method described later. The taking of the samples was carefully timed to coincide with points at the sea surface at which SeaSoar would subsequently surface. The following conductivity ratio equation was calculated from the first few salinity samples collected at the start of the SeaSoar surveying and was used for all the SeaSoar surveys :-

$$C_1 = (C_{\text{raw}} * 0.001) * 1.0035640$$

Salinity was calculated from conductivity, pressure and temperature using the 1983 equation of state for sea-water. Further corrections were applied, in the form of offsets in salinity. Salinity offsets in the data from SeaSoar surveys 1 and 2, described in the introduction, were calibrated according to the analysed surface salinities as follows :-

file:-	gr510bc	data cycle:-	1-2756	offset:-	0.000
			2757-end		-0.010
	gr510cd		1-1300		-0.010
			1301-end		-0.025
	gr510de		all		-0.025
	gr510eh		1-1508		-0.025
			1509-end		-0.040

	gr510tu		all		-0.060
	gr510ux		all		-0.060
	gr510xz		all		-0.060

Salinity offsets for data from SeaSoar surveys 3, 4 and 5 were identified by comparing T/S profiles with a T/S scatter plot of all the data from the large scale IFF survey, survey 2. Salinity offsets made to fine scale survey data as follows:-

file:-	gr51f1tt	raw files:-	all	offset:-	-0.070
	gr51f2tt	(d. cycles)	ss51085		-0.080
			ss51086-51089		-0.080

			ss51096-51098		-0.075

	ss51099	
	(1-4135)	-0.075
	(4136-4471)	-0.040
	(4472-4558)	-0.050
	(4559-end)	-0.080
	ss51100-51101	-0.080
gr51f3tt	ss51102	
	(1-4826)	-0.080
	(4827-5200)	-0.060
	(5201-end)	-0.080
	ss51103-51111	-0.080
	ss51112	
	(1-14517)	-0.080
	(14518-15048)	-0.067
	(15049-16921)	-0.080
	(16922-18837)	-0.082

Following this procedure, absolute errors in salinity are estimated to be ± 0.01 psu.

CTD DATA

The CTD system employed during this cruise was the same as that on the preceding cruise: Charles Darwin 50, and the same processing and analytical techniques were used for the data collection and sample analysis. Full details of these are given by Saunders et al (1991) and are only described briefly here.

Eighteen full depth CTD stations were worked in two sections (Fig.1, Table 1). The instrumentation consisted of a NBIS Mark 3 CTD with Beckman oxygen sensor and a rosette with twelve 10 litre Niskin bottles. Four bottles were fired on each station and water samples were collected and analysed for dissolved oxygen content and salinity. These values were then used to calibrate the conductivity and oxygen sensors.

SAMPLE ANALYSIS

Oxygen samples were drawn from the Niskin bottles first and were analysed using the Winkler titration procedure, as described by Saunders et al (1991). A new SIS automated photometric end-point detection system was used but due to a faulty connector air was drawn into the supply of titre from the

burette to the sample. About a quarter of the samples were lost through this problem. From the 109 samples successfully analysed 32 duplicate pairs were obtained of which the mean difference was less than 0.01 ml/l with a standard deviation of 0.004 ml/l.

Salinity samples were analysed using a Guildline Autosal model 8400 bench salinometer, which was sited in the controlled temperature laboratory on the *RRS Charles Darwin*. The salinometer was operated at a temperature of 21°C in a 20°C environment. A total of 136 samples were drawn from the Niskin bottles and analysed providing 67 duplicate pairs. The mean difference between pairs of samples was 0.0006 psu with standard deviation of 0.0007 psu.

CTD SENSOR CALIBRATION

CTD data were collected from the deck unit and transferred to Pstar in the same way as SeaSoar data. Calibration data for comparison with the bottle samples were collected when the multisampler was fired and saved on the CTD deck unit. These were transferred to Pstar later. Processing of the data followed the path described by King et al (1991) and the following corrections were applied:

Pressure

The calibration for pressure was determined by laboratory measurements. Three corrections were applied:

$$P_1 = (P_{\text{raw}} * 0.1) * 0.9989873 - 4.69$$

A further correction was made for the effect of temperature on the CTD pressure offset:

$$P = P_1 - 0.4 (\text{tlag}(400) - 12)$$

where tlag is a lagged temperature in degrees C constructed from the CTD temperature with a time constant of 400 seconds. The values of 400 seconds and 0.4 db/°C are based on laboratory tests.

The upcast was also corrected for hysteresis resulting from the loading and unloading of the sensor. This was calculated from laboratory measurements of a 5500 db simulated cast (Table 2).

$$P_{\text{new}} = P - [\text{DP5500}(P) - (P/P_{\text{max}} * \text{DP5500}(P_{\text{max}}))]$$

Temperature

The platinum resistance thermometer was calibrated in the laboratory:

$$T = (T_{\text{raw}} * 0.0005) * 0.9985949 - 0.01177486$$

where raw temperature was calculated using a time constant (deltat) of 0.22 to compensate for the different response times of the temperature and conductivity sensors.

Conductivity

An initial conductivity ratio was calculated from the first few salinity samples collected, this was used for the first nine stations. For stations 10 -18 the coefficients were revised after further comparison with sample data.

Stations 1 - 9: $C_1 = (C_{\text{raw}} * 0.001) * 0.995478$

Stations 10 - 18: $C_1 = (C_{\text{raw}} * 0.001) * 0.995595$

Conductivity was further corrected for the effects of pressure and temperature:

$$C = C_1 * [1 + 1.5e^{-8} * (\text{press} - 0) - 6.5e^{-6} * (\text{temp} - 15)]$$

Salinity was calculated from conductivity, pressure and temperature using the 1983 equation of state for sea-water. Further corrections were applied, in the form of offsets, after comparison with the bottle samples. These are listed in Table 3.

Oxygen

Dissolved oxygen was calculated using the equation:

$$O = O_{\text{sat}}(T, S) * r * \text{oxyC} * \exp(a \text{ oxyT} + b \text{ press})$$

where the coefficients a, b, and r were obtained by a least squares regression of $\ln(\text{oxysamp}/(\text{oxyC} * O_{\text{sat}}))$. Only four samples were drawn on each station, too few to calculate coefficients for each cast. The entire data set was used giving $r = 1.536171$, $a = -.04140$ and $b = 0.0001595$. These coefficients fitted the oxygen profiles to the sample data reasonably accurately on stations 1 - 9. Between

stations 9 and 10 the CTDO unit was left unused on deck for 4 days and on station 10 and succeeding stations the fit between samples and oxygen was poor. To compensate r was adjusted gradually through stations 10 - 14 until it returned to 1.536171 on station 15.

10:	$r = 1.42$	($a = -.041$, $b = 0.00016$)
11,12:	$r = 1.48$	($a = -.041$, $b = 0.00016$)
13:	$r = 1.50$	($a = -.041$, $b = 0.00016$)
14:	$r = 1.51$	($a = -.041$, $b = 0.00016$)

DATA PRESENTATION

CTD data are presented in the form of listings at standard depths, together with profiles of potential temperature against salinity and potential temperature against oxygen. Contoured plots of potential temperature, salinity, oxygen and density versus depth are also presented for the two CTD sections.

SeaSoar data are presented as contoured sections of salinity against density and potential temperature, density, salinity, sound speed and cross-track geostrophic velocity (ref. level 400 m) against depth. Each leg is plotted separately as indicated in the title eg. gr51snbc, gr51f1snkl where the last two letters refer to the end points of the leg (Figures 1, 2, 3 and 4). The inclusion of the letter "f" and following number in the title indicates which fine scale survey. It should be noted that the fine scale survey sections are plotted against an expanded horizontal (latitude) scale.

ACKNOWLEDGEMENTS

CD51 succeeded in carrying out one more SeaSoar survey than planned, enabling the study of a considerably longer time sequence of in-situ data than would otherwise have been possible. This was, at least in part, a result of the eager and proficient assistance of the Master, Officers and crew of RRS Charles Darwin and of the enthusiastic support of John Smithers, Steven Keene and Robert Wallace, keeping SeaSoar flying; all of whom are here gratefully acknowledged.

Our thanks also to Louise Fuger and Alison Chadwick for their help in making this report camera ready.
