- 51 A reconnaissance geochemical survey of Anglesey
- 52 Miscellaneous investigations on mineralisation in sedimentary rocks
- 53 Investigation of polymetallic mineralisation in Lower Devonian volcanics near Alva, central Scotland
- 54 Copper mineralisation near Middleton Tyas, North Yorkshire
- 55 Mineral exploration in the area of the Fore Burn igneous complex, south-western Scotland
- 56 Geophysical and geochemical investigations over the Long Rake, Haddon Fields, Derbyshire
- 57 Mineral exploration in the Ravenstonedale area, Cumbria
- 58 Investigation of small intrusions in southern Scotland
- 59 Stratabound arsenic and vein antimony mineralisation in Silurian greywackes at Glendinning, south Scotland
- 60 Mineral investigations at Carrock Fell, Cumbria. Part 2—Geochemical investigations
- 61 Mineral reconnaissance at the Highland Boundary with special reference to the Loch Lomond and Aberfoyle areas
- 62 Mineral reconnaissance in the Northumberland Trough
- 63 Exploration for volcanogenic sulphide mineralisation at Benglog, North Wales
- 64 A mineral reconnaissance of the Dent-Ingleton area of the Askrieg Block, northern England
- 65 Geophysical investigations in Swaledale, North Yorkshire
- 66 Mineral reconnaissance surveys in the Craven Basin
- 67 Baryte and copper mineralisation in the Renfrewshire Hills, central Scotland
- 68 Polymetallic mineralisation in Carboniferous rocks at Hilderston, near Bathgate, central Scotland
- 69 Base metal mineralisation associated with Ordovician shales in south-west Scotland
- 70 Regional geochemical and geophysical surveys in the Berwyn Dome and adjacent areas, North Wales
- 71 A regional geochemical soil investigation of the Carboniferous Limestone areas south of Kendal (south Cumbria and north Lancashire)
- 72 A geochemical drainage survey of the Preseli Hills, south-west Dyfed, Wales

On 1 January 1984 the Institute of Geological Sciences was renamed the British Geological Survey. It continues to carry out the geological survey of Great Britain and Northern Ireland (the latter as an agency service for the government of Northern Ireland), and of the surrounding continental shelf, as well as its basic research projects; it also undertakes programmes of British technical aid in geology in developing countries as arranged by the Overseas Development Administration.

The British Geological Survey is a component body of the Natural Environment Research Council.

## SUMMARY

The soils of four separate areas lying within the outcrop of the Lower Carboniferous Limestone to the south and southwest of Kendal were sampled and analysed for copper, lead, zinc, barium and manganese.

Mining activity in the areas has been of little significance; restricted to a small number of disused trials for iron and two old lead mines at Brigsteer and Whitbarrow. Significant geochemical anomalies are few and can be related to either artificial contamination, association with minor iron mineralisation or to the reefal limestones that occur in the south of the area. The latter are of greatest significance in view of the similarities with areas along the Craven Fault system to the east and the association of economic mineralisation in Carboniferous reefs in Ireland.

## INTRODUCTION

The area covered by this investigation is shown in Figure 1 and can be divided into four separate areas each of which lies within the outcrop of Lower Carboniferous Limestone. They are as follows:-

- Area I      Whitbarrow and Brigsteer
- Area II     Hutton Roof
- Area III    Over Kellet and Nether Kellet
- Area IV    Warton Crag, Silverdale, Arnside and Beetham

The last major geological mapping was completed at the end of the 19th century and the map drawn for this report (Figure 2) is a simplified compilation from 1 mile to the inch geological sheets 91 NE, 98 SE and 98 NE. The four areas investigated are essentially bedrock inliers in a region of much glacial drift cover.

There has been little metalliferous mineral exploration in the survey area although there are records of old mining operations for lead at Brigsteer and Whitbarrow (Wildridge 1975, p. 36). A number of disused iron workings are located within the area though these are small and insignificant compared with those of the established iron mining field around Millom and Dalton-in-Furness (Rose and Dunham, 1977).

This investigation was undertaken to examine the area for any evidence of base metal mineralisation associated with, in particular, structures affecting parts of the Carboniferous succession. There are several factors in the survey area similar to those associated with the 'Irish-type' base metal mineralisation; namely, the faulting of Carboniferous carbonate successions against Lower Palaeozoic rocks and the occurrence of reef-like limestone facies e.g. at Halton Green [SD 521 654] and Swantley [SD 523 677].

## GEOLOGY

The geological information on this area dates from the 1870s and is based upon the work of Aveline and others (1872).

The oldest rocks assigned to the Carboniferous are Basement Conglomerates exposed in two fault bounded blocks to the north and north-east of Kirkby Lonsdale.

They consist primarily of coarse conglomerates with occasional impersistent sandstones and nowhere is the relationship between these beds and the younger carbonaceous sequence observed.

The Carboniferous carbonates (mainly of Visean age) occupy the western and central part of the area and are generally compact grey-blue limestones typical of deposition in a shelf environment. They form striking topographical features with extensive scar cliffs and well-developed limestone pavement. There are two predominant joint directions across the area striking 150° and 060°. To the south of Carnforth, although exposures are poor due to widespread glacial drift, the evidence of reefal limestones suggests that a more basinal facies may be developed to the south.

Younger sediments of the Carboniferous (representing Namurian and Westphalian) occur in the south and south-east and consist of an alternating succession of thin limestones, sandstones and shales passing upwards into more arenaceous beds. These are overlain by a sequence of shales, sands, seat earths and coals typical of the Coal Measures.

The structure of the area is dominated by the fault system which includes two dominant trends approximately N-S and NW-SE, the latter being of greater significance in the southern part of the area. In the east of the area the North Craven Fault appears continuous with the northerly trending Dent Fault system; in the south the main NW-SE faults may be a continuation of the line of the Mid and South Craven Faults marking the hinge line between the shelf and basin depositional environments.

Except adjacent to faults the strata have a general 10 to 20° easterly dip but there is local flexuring into broad folds. The most extensive of these, the Priest Hutton monocline is identifiable from Slyne [SD 480 660] through Bolton-le-Sands to Priest Hutton. The eastern limb of this structure is steeply inclined, coinciding with an extensive zone of north-south faulting against which the structure terminates to the north-east.

Regional geophysical data are available for the area in the form of Bouguer anomaly and regional magnetic data (Institute of Geological Sciences, 1972, 1977). The Bouguer values show no obvious features that can be related to the margin of the Carboniferous basin or to the thickness of the Carboniferous sediments, presumably reflecting the lack of contrast between the Lower Palaeozoic and Carboniferous sediments. A series of small north-south trending positive anomalies can be identified (J. D. Cornwell, oral comm. 1978) on a residual Bouguer anomaly map, coincident with the line of the Priest Hutton monocline.

The aeromagnetic map of Great Britain shows that a small magnetic high (values in excess of 30 gammas) underlies the area and is continuous eastwards with a feature attributed to the Wensleydale Granite. Evans and Maroof (1976) suggest that the positive feature to the west and south-west of Kendal may be an extension at depth of the Wensleydale granite.

## METHODS OF INVESTIGATION

The areas of investigation, because of the limestone bedrock, have poor or no development of surface drainage. The usual method of regional reconnaissance

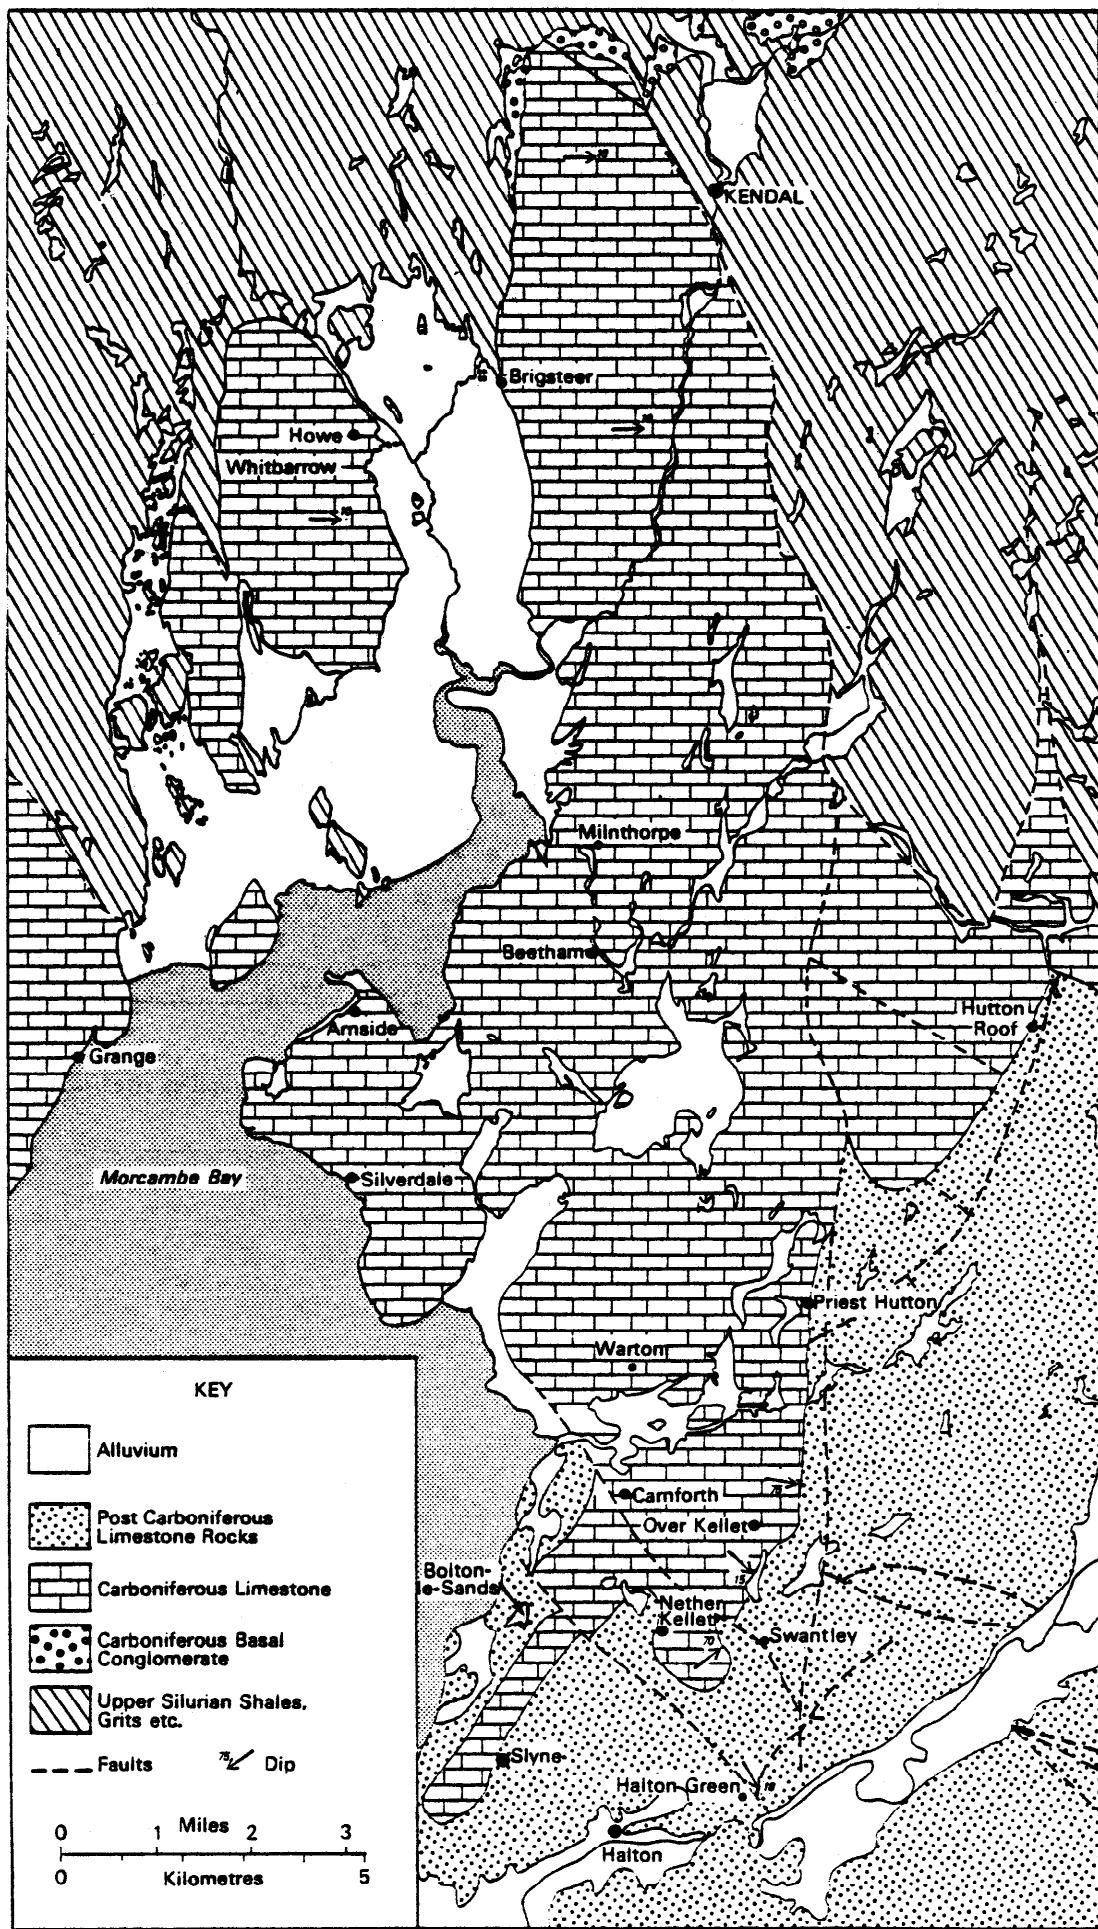

Figure 2 Geological map of the survey area.

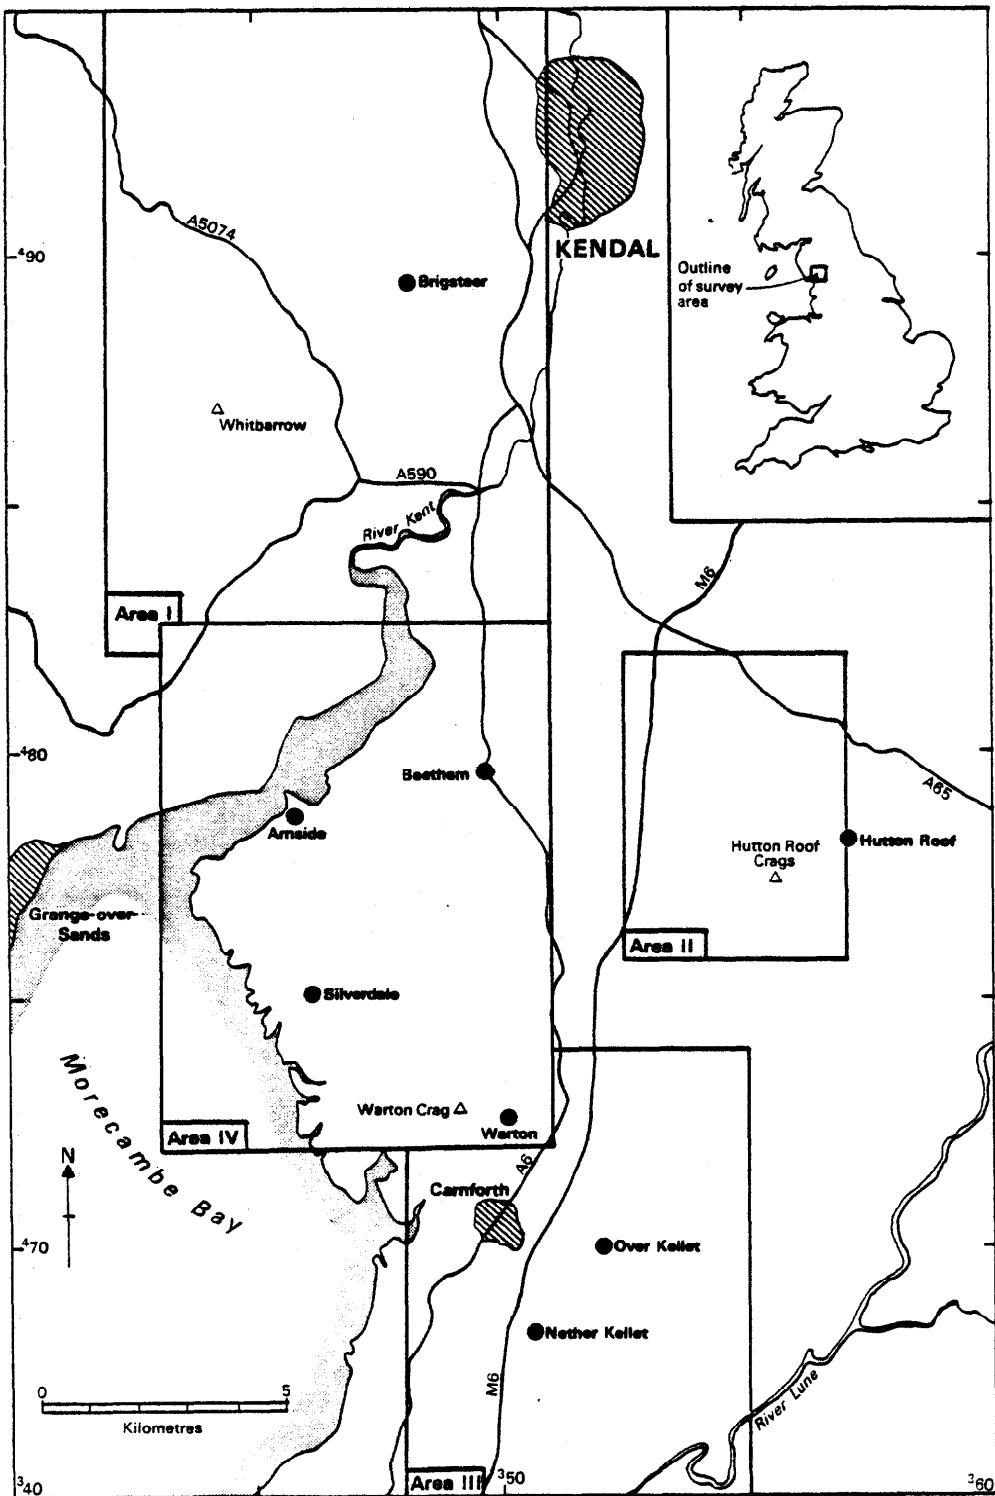

Figure 1 Map of the survey area.

by a drainage basin survey was therefore inapplicable. Instead, a regional soil survey was undertaken based (where practicable) on east-west sampling lines spaced 300 m apart, sampling along each line being at 250 m intervals. Area I and parts of Area IV (Warton Crag and Arnside) were used to test the effectiveness of this method of regional investigation; Areas II and III, and the remainder of Area IV were investigated subsequently. Soil samples were collected, using a 1 m screw auger, from the B horizon of the soil. However, particularly on the limestone plateau areas, soil profile development was poor and these thin soils were sampled with a hand trowel. Figures 3 to 6 show the sampling grid and an indication of depth of sampling from the four areas.

The minus 85-mesh fraction of the soils from the orientation survey (Areas I and parts of Area IV) were

analysed by AAS for Cu, Pb, Zn, Ba and Mn at the commercial laboratories of Mather Research Ltd., Rothbury. Samples collected from Areas II and III, and from the remainder of Area IV, were analysed by XRF for the same elements at the laboratories of the Institute in London.

## RESULTS

Locational and chemical data are listed in the Appendix. Results are presented as isopleth maps (see Figures 7 to 26). The class intervals have been calculated from cumulative probability plots partitioned in the manner described by Sinclair (1976), and the choice of intervals is designed to give the maximum definition of geochemical anomalies.

## DISCUSSION OF RESULTS

### Area I (Whitbarrow and Brigsteer)

There are no exceptionally high levels of copper, lead, zinc, barium or manganese recorded in this area (Table 1). Some of the highest values for these elements, particularly lead and zinc, are recorded on the east side of Whitbarrow (see Figures 7 to 11), where field investigation identified a disused iron mine [SD 4370 8775]. At this locality (Bell Rake) a 0.5 m wide vein of calcite possibly with some baryte is seen in the roof of an old portal. This isolated vein strikes 140° and is vertical. This is possibly the locality described in a transcript dated 1616 quoted by Wildridge (1975).

"The other place called Whitbarrow Hills, where several dead leaders appear, with hingett and liggett.

This hath not been wrought to such profile as were fit, but some further trial were made about it some 10 fathoms deep..... undoubtedly a vein will be found, which by the nature of the stone of these works we conceive will come a lead oare mixt with copper".

No copper, lead or zinc minerals were seen either at outcrop or in mine dump material during a visit to this site. It is probable that this site was excavated in the belief that it was associated with a metal-containing lode vein.

**Table 1** A summary of analytical data for the soils from the Whitbarrow and Brigsteer area (Area I) (taken from cumulative probability plots, Figures 7-11).  $\bar{x}$  is the geometric mean and  $\sigma$  the standard deviation. Chemical analyses by AAS.

Element	Population	$\bar{x}$	$\bar{x} - \sigma$	$\bar{x} + \sigma$	$\bar{x} + 2\sigma$
Barium	Single	175	129	237	321
	A (41 %)	275	245	310	344
Lead	B (59 %)	203	169	242	288
	A (44 %)	94	44	198	410
Zinc	B (56 %)	35	24	52	73
	A (42 %)	155	80	300	580
Copper	B (58 %)	82	62	105	138
	Single	15	8	31	63
Manganese	A (25 %)	2100	1205	3800	6500
	B (75 %)	630	380	1100	1620

In the area east of the mine across to Slape Scar [SD 446 875] and on to Howe [SD 456 884] several samples with anomalous values for Zn, Pb and Ba define a north-westerly trending zone. The only indication of mineralisation in this area is given by small calcite veins up to 1 cm across that run 040-060°, i.e. parallel to one of the main joint directions in the limestone.

Elsewhere in Area I anomalous values for single elements occur as isolated anomalies. There is much similarity between the distribution of lead and of zinc and these metals show some spatial correlation with the depth of soil sampled. The thin soils of the limestone pavement areas have higher lead and zinc contents than the deeper soils which, with their better developed profiles have a more acidic character in which these elements become relatively more mobile than in the thin soils of the pavements.

### Area II (Hutton Roof)

Despite the poor development of soils over much of this area a complete regular sampling grid was maintained excluding the limestone quarry area at SD 534 788. With the exception of those for copper, the data for each element can be partitioned into two populations (Table 2). This possibly reflects the two soil types sampled, i.e. one population being representative of the poorly developed soils on the limestone pavement areas

**Table 2** A summary of analytical data for the soils from the Hutton Roof area (Area II) (taken from cumulative probability plots, figures 12-16).  $\bar{x}$  is the geometric mean and  $\sigma$  the standard deviation. Chemical analyses by XRF.

Element	Population	$\bar{x}$	$\bar{x} - \sigma$	$\bar{x} + \sigma$	$\bar{x} + 2\sigma$
Barium	A (41 %)	275	245	310	344
	B (59 %)	203	169	242	288
Lead	A (44 %)	94	44	198	410
	B (56 %)	35	24	52	73
Zinc	A (42 %)	155	80	300	580
	B (58 %)	82	62	105	138
Copper	Single	15	8	31	63
	A (25 %)	2100	1205	3800	6500
Manganese	B (75 %)	630	380	1100	1620

and the other representing the better developed soils of pasture land. As is seen in Area I, the high lead and zinc values tend to be associated with the poorly developed soils. Barium values, however, seem to be highest in areas where the soil is better developed around the margins of the limestone crags.

There are no high value anomalies and copper, with 70 per cent of the soils containing 20 ppm Cu or less, is deficient over much of the area. Most of the highest values of Cu, Pb, Zn and Mn occur in the southeast around the triangulation station on Hutton Roof [SD 5560 7745]. The element distribution maps suggest a north-easterly trending feature as defined by these anomalies, with a possible north-south component identified in the Cu distribution. At the locality called Blasterfoot Gap [SD 566 783] values of 152 and 650 ppm are recorded for copper, which are significantly high against the generally low copper background. Minor calcite veining is observed running approximately NE-SW, parallel to the Blasterfoot Gap which may represent a dip fault with a small amount (a few metres) of displacement. From their recent work, Vincent and Lee (1981) have observed loess deposits within this area [SD 555 787] but the results presented in this survey do not indicate whether the chemical data can be used to identify loess accumulation on the limestone outcrop. The age suggested by Vincent and Lee (1981) for the deposition of the loess is late Devensian which allows sufficient time for the chemical signature of any mineralisation in subcrop to become reflected in the material at the base of a soil profile.

### Area III (Over Kellet and Nether Kellet)

Unlike the other three areas studied, much of Area III is characterised by well-developed deep soils and very few rock outcrops. The greater uniformity of soil type is probably reflected in the much narrower ranges of element concentrations (see Table 3). A regular sampling grid was maintained across the survey area with the exception of the limestone quarry areas to the north and east of Nether Kellet [SD 6850].

There are no outstandingly high anomalies though there are several areas where high values are interpreted as significant. The highest lead values occur in the south of the area at Halton [SD 504 654] and east of Halton Green [SD 516 653] where, near the locality called Higher Cliff Wood [SD 521 654], there is an outcrop of reefal limestone which lends support to the possibility that this part of the area lies on or close to a hinge line that separates platform from more basinal facies. This line may be a westward extension of the South Craven fault system.

**Table 3** A summary of analytical data for the soils from the Over Kellet and Nether Kellet area (Area III) (taken from cumulative probability plots, Figures 17-21).  $\bar{x}$  is the geometric mean and  $\sigma$  the standard deviation. Chemical analyses by XRF.

Element	Population	$\bar{x}$	$\bar{x} - \sigma$	$\bar{x} + \sigma$	$\bar{x} + 2\sigma$
Barium	Single	277	238	323	376
Lead	A (14 %)	57	42	78	107
	B (86 %)	32	25	40	50
Zinc	A (72 %)	61	48	78	120
	B (28 %)	41	30	56	75
Copper	A (84 %)	18	12	26	39
	B (16 %)	6	4	10	14
Manganese	A (75 %)	660	370	1160	2050
	B (25 %)	150	122	245	348

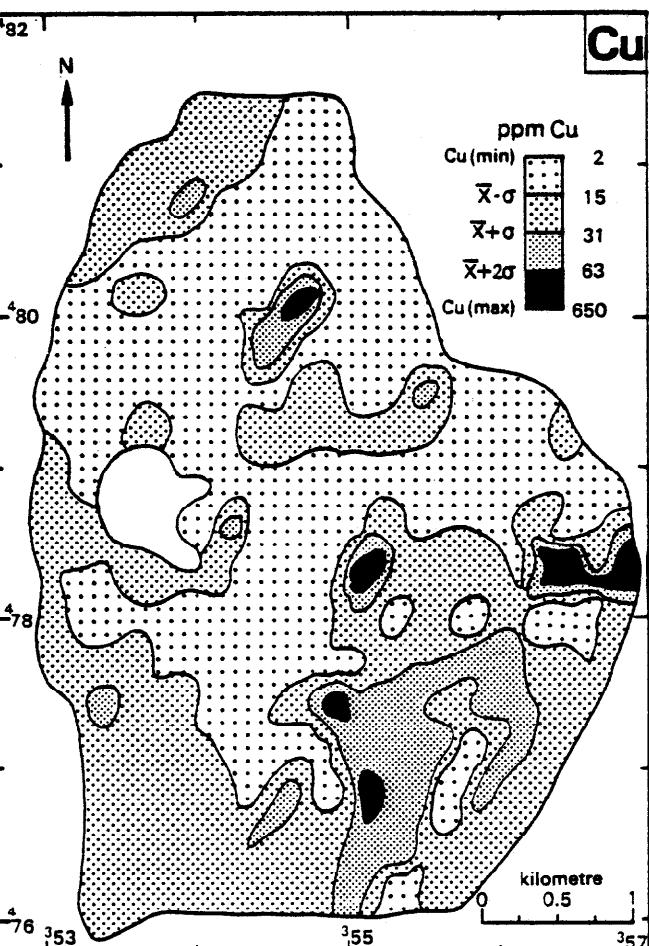

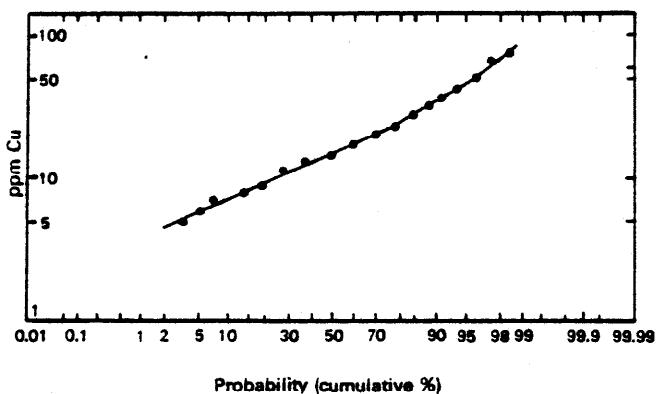

At Swantley [SD 523 677] there is a well-defined copper and manganese anomaly with a minor zinc high. During reconnaissance soil sampling the outcrop at this locality was investigated. This prominent escarpment feature is composed primarily of rubbly limestones with only a few distinct bedding features that indicate variable dip direction in excess of  $45^\circ$ . Accumulations of crinoidal and productid fragments, and its generally rubbly appearance, identify the outcrop as a debris deposit associated with a reef. The generally very porous character of this carbonate is indicated by the considerable amount of secondary quartz that has invaded the rock. This is accompanied along some faults and joints by veinlets containing iron, copper and lead minerals. On the scarp where a gully has been cut there are quite distinct surface coatings of azurite and malachite also evidently supergene.

A line of soil samples was collected above and below the limestone crags at Swantley. Maximum values for Pb, Zn and Cu were 6141, 183 and 765 ppm respectively.

The authors can find no reference to this mineralisation at Swantley, which has clearly been worked in the past. The presence of metalliferous mineralisation at this locality is indicated by the reconnaissance soil survey, confirming the suitability of this technique; hence isolated anomalies in other areas must be worthy of some further study if one such anomaly is attributable to mineralisation like that at Swantley. There are also isolated highs at Capernwray [SD 530 719], Over Kellet [SD 523 701], Swarthdale [SD 528 690] and Stub Hall [SD 507 668].

There is no observable mineralisation at Capernwray and Over Kellet, and these anomalies are probably the result of artificial contamination. The isolated anomalies at Swarthdale and Stub Hall similarly have no observable surface expression; both are similar smooth ridge-like features with no rock outcrops. At both localities the surface soils contain small boulders of sandstone with no carbonate material, suggesting a sandstone bedrock. Therefore, the slightly increased values of Cu, Pb and Ba possibly reflect a lithological change. The cause of the high values for Pb, Zn and Ba at a location to the north of Halton [SD 504 654] remains unresolved.

**Area IV (Warton Crag, Silverdale, Arnside and Beetham)** This was the most difficult of the four areas to sample because of large areas of dense woodland. Much of the area was sampled in a non-systematic way with sample sites being accepted where access was convenient; but overall a similar density of sampling to the other areas was maintained.

**Figure 12** A distribution map of copper in the soils from Hutton Roof (Area II).

The interpretation of the geochemical data also presented a problem. The initial samples (from Warton Crag and Arnside) were analysed by the AAS technique whereas those from Silverdale, Arnside and Beetham were done by XRF. For lead, zinc and copper the different methods of analysis was of little consequence as both produced data sets with similar means and ranges. Barium determined by AAS, as might be expected, gave rise to lower results than those produced by XRF as the acid dissolution used is not suitable for extracting total barium. Manganese, on the other hand, was generally higher in the AAS than the XRF determined samples with a much greater range of values being reported. All the data for copper, lead and zinc were considered together and treated as for the other areas (Figures 22 to 24). The AAS and XRF results for manganese and barium are considered as two separate

**Table 4** A summary of analytical data for the soils from Warton Crag, Silverdale, Arnside and Beetham (Area IV) (taken from cumulative probability plots, Figures 22-26).  $\bar{x}$  is the geometric mean and  $\sigma$  the standard deviation.

Element	Method of analysis	Population	$\bar{x}$	$\bar{x} - \sigma$	$\bar{x} + \sigma$	$\bar{x} + 2\sigma$

Warton Crag	SD 488 724	Ba, Cu, Pb	Disused iron workings
Slack Head	SD 491 789	Pb, Zn	Cause not known
Major Woods	SD 491 782	Pb, Zn	Cause not known
Creep-i'-th'-call Bridge	SD 476 782	Pb, Zn	Cause not known

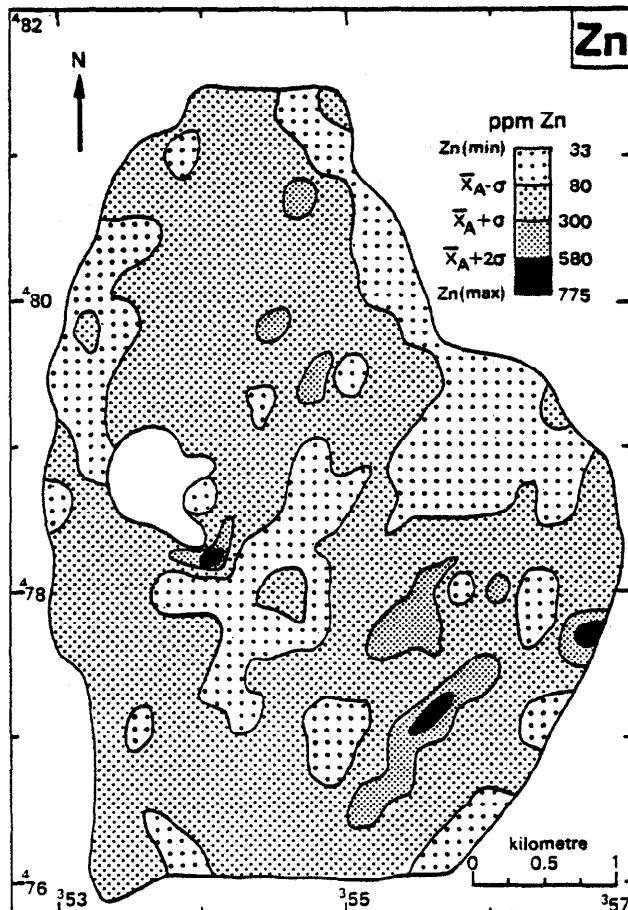

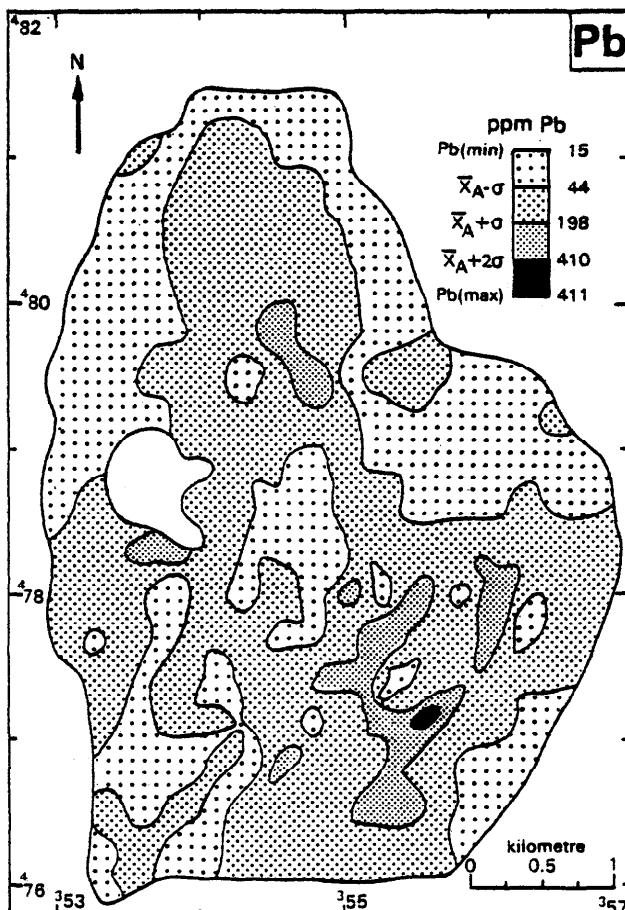

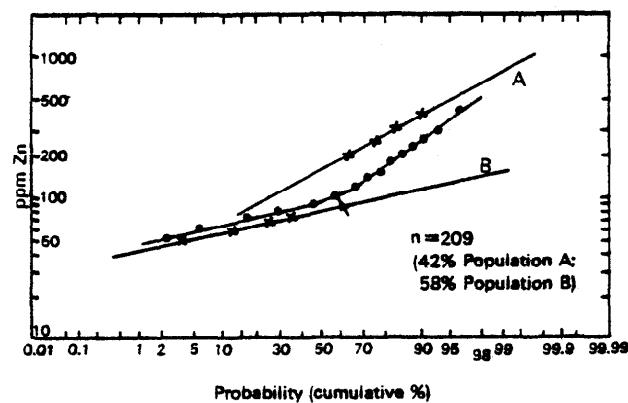

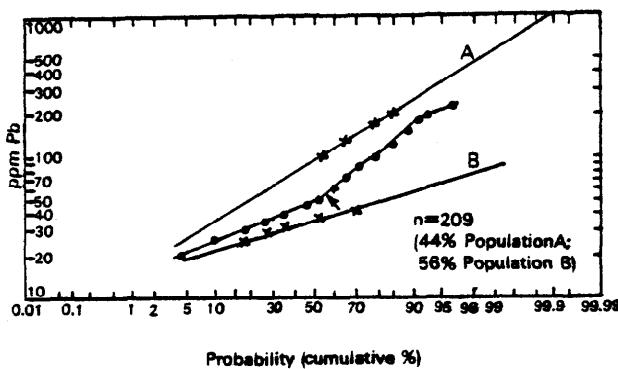

Figure 13 A distribution map of lead in the soils from Hutton Roof (Area II).

sets of data with class intervals being determined using means and standard deviations from the two cumulative probability plots (Figures 25 to 26).

Copper, as in the other areas, is generally low across the entire area with 90 per cent of the soils sampled containing less than 30 ppm Cu. There are no outstandingly high values reported for any of the elements (Table 4), though there are several localities where high values for more than one element are coincident.

- (i) West of Warton at SD 488 724, by a disused shaft, all elements (and particularly lead and copper) are high. This disused shaft appears to have been associated with iron working and there is no evidence of copper, lead or zinc minerals in outcrop.

Figure 14 A distribution map of zinc in the soils from Hutton Roof (Area II).

- (ii) Southwest of Arnside [SD 439 773], again adjacent to what appears to be disused iron workings, manganese, zinc and barium are enriched. Indeed, in the Arnside area where there is much evidence of old iron workings, levels of all elements are generally higher than elsewhere.
- (iii) There is a number of coincident lead and zinc highs in the area from Slack Head [SD 491 791] (south of Beetham) south-westwards to Creep-i'-th'-call Bridge [SD 475 782]. No evidence of the cause of these relatively high lead/zinc values can be seen from surface exposures, but the general trend of the anomalies suggests that they could be related to minor calcite mineralisation along a major joint direction (060°).

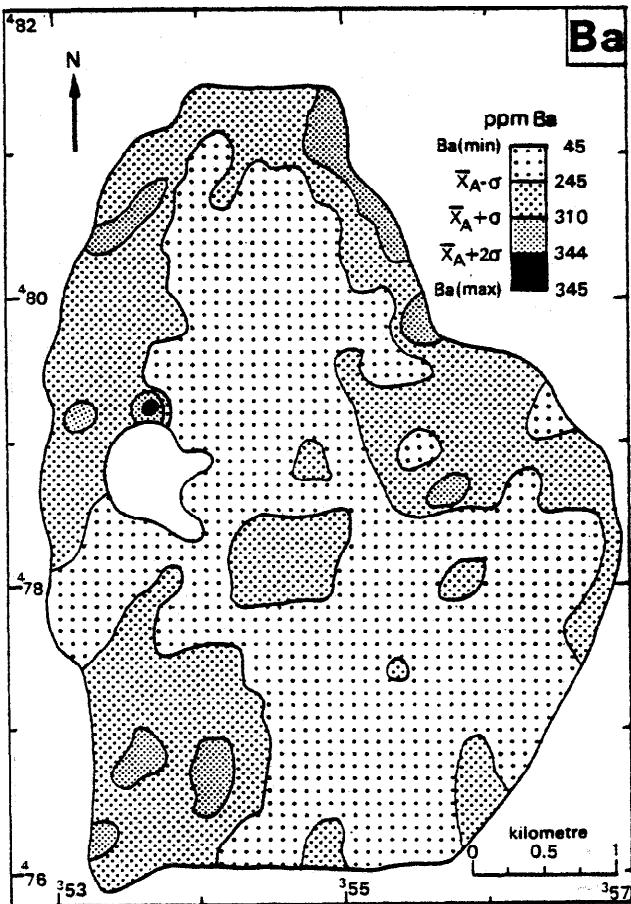

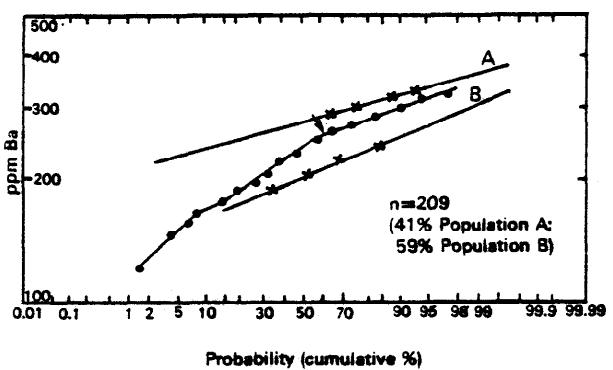

Figure 15 A distribution map of barium in the soils from Hutton Roof (Area II).

#### CONCLUSIONS AND RECOMMENDATIONS

The disposition of geochemically anomalous areas is summarised in Table 5, mainly on the basis of localities where there is coincidence between the highest values of more than one element. The anomalies can be divided into three groups:-

- (i) Anomalies possibly associated with reefal limestones.
- (ii) Anomalies associated with iron-rich limestones, particularly in areas where there are disused iron workings.

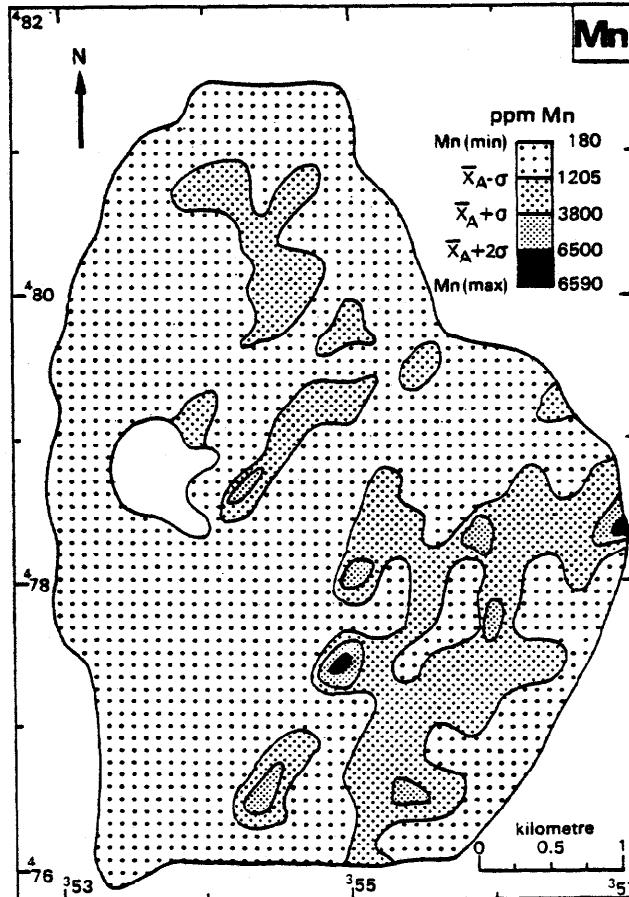

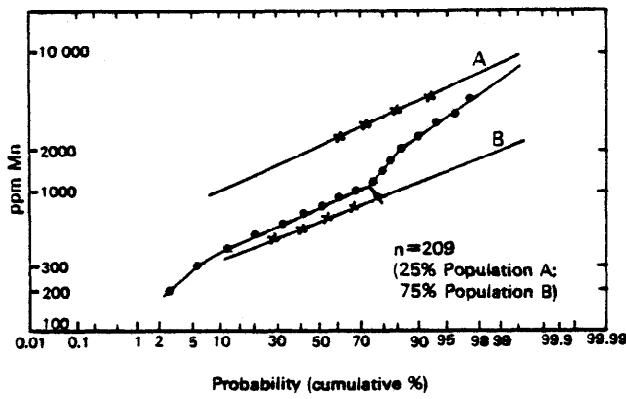

Figure 16 A distribution map of manganese in the soils from Hutton Roof (Area II).

- (iii) Anomalies for which there is no obvious geological explanation and which are likely to be the result of pollution.

Of the three groups, the anomalies possibly associated with areas underlain by reefal limestones are the most significant in view of similarities with areas along the Craven Fault System to the east (Wadge and others, 1983) and the association of economic mineralisation with Carboniferous reefs of Ireland. It is recommended that these anomalies be followed up using a denser soil sampling grid.

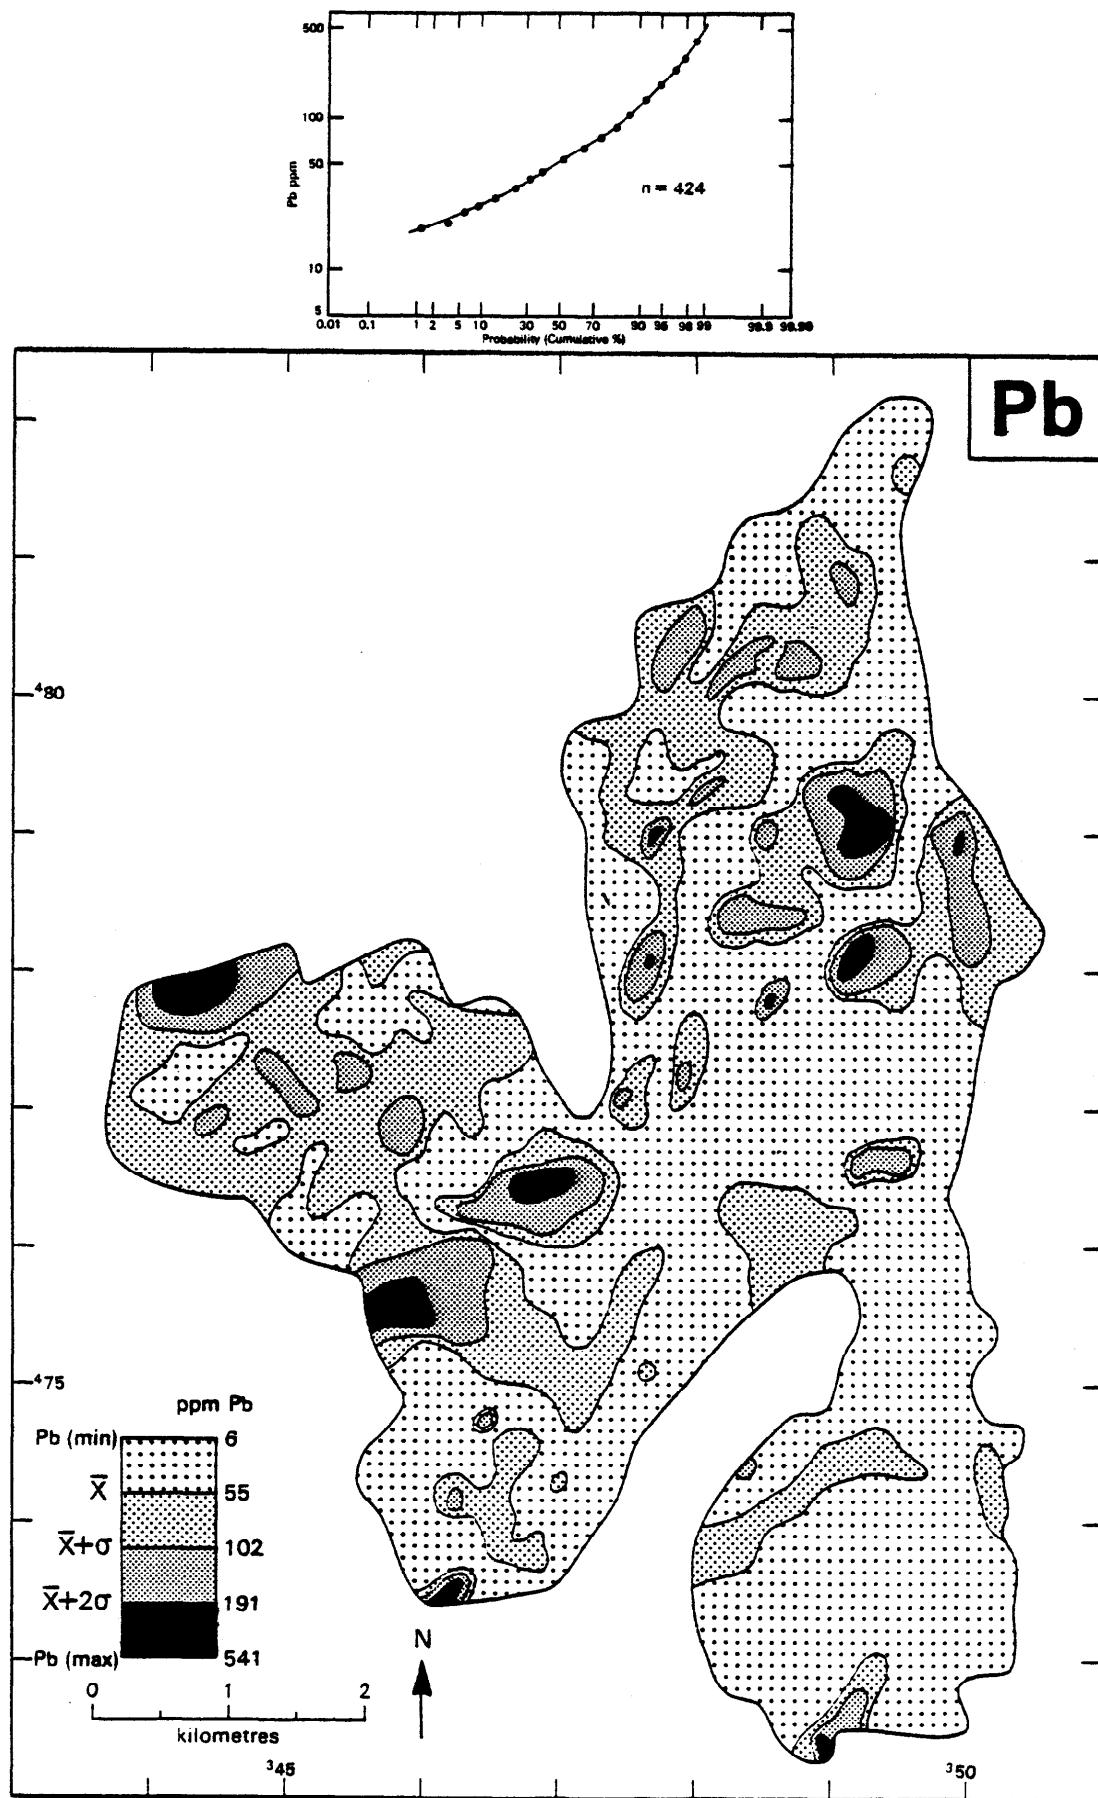

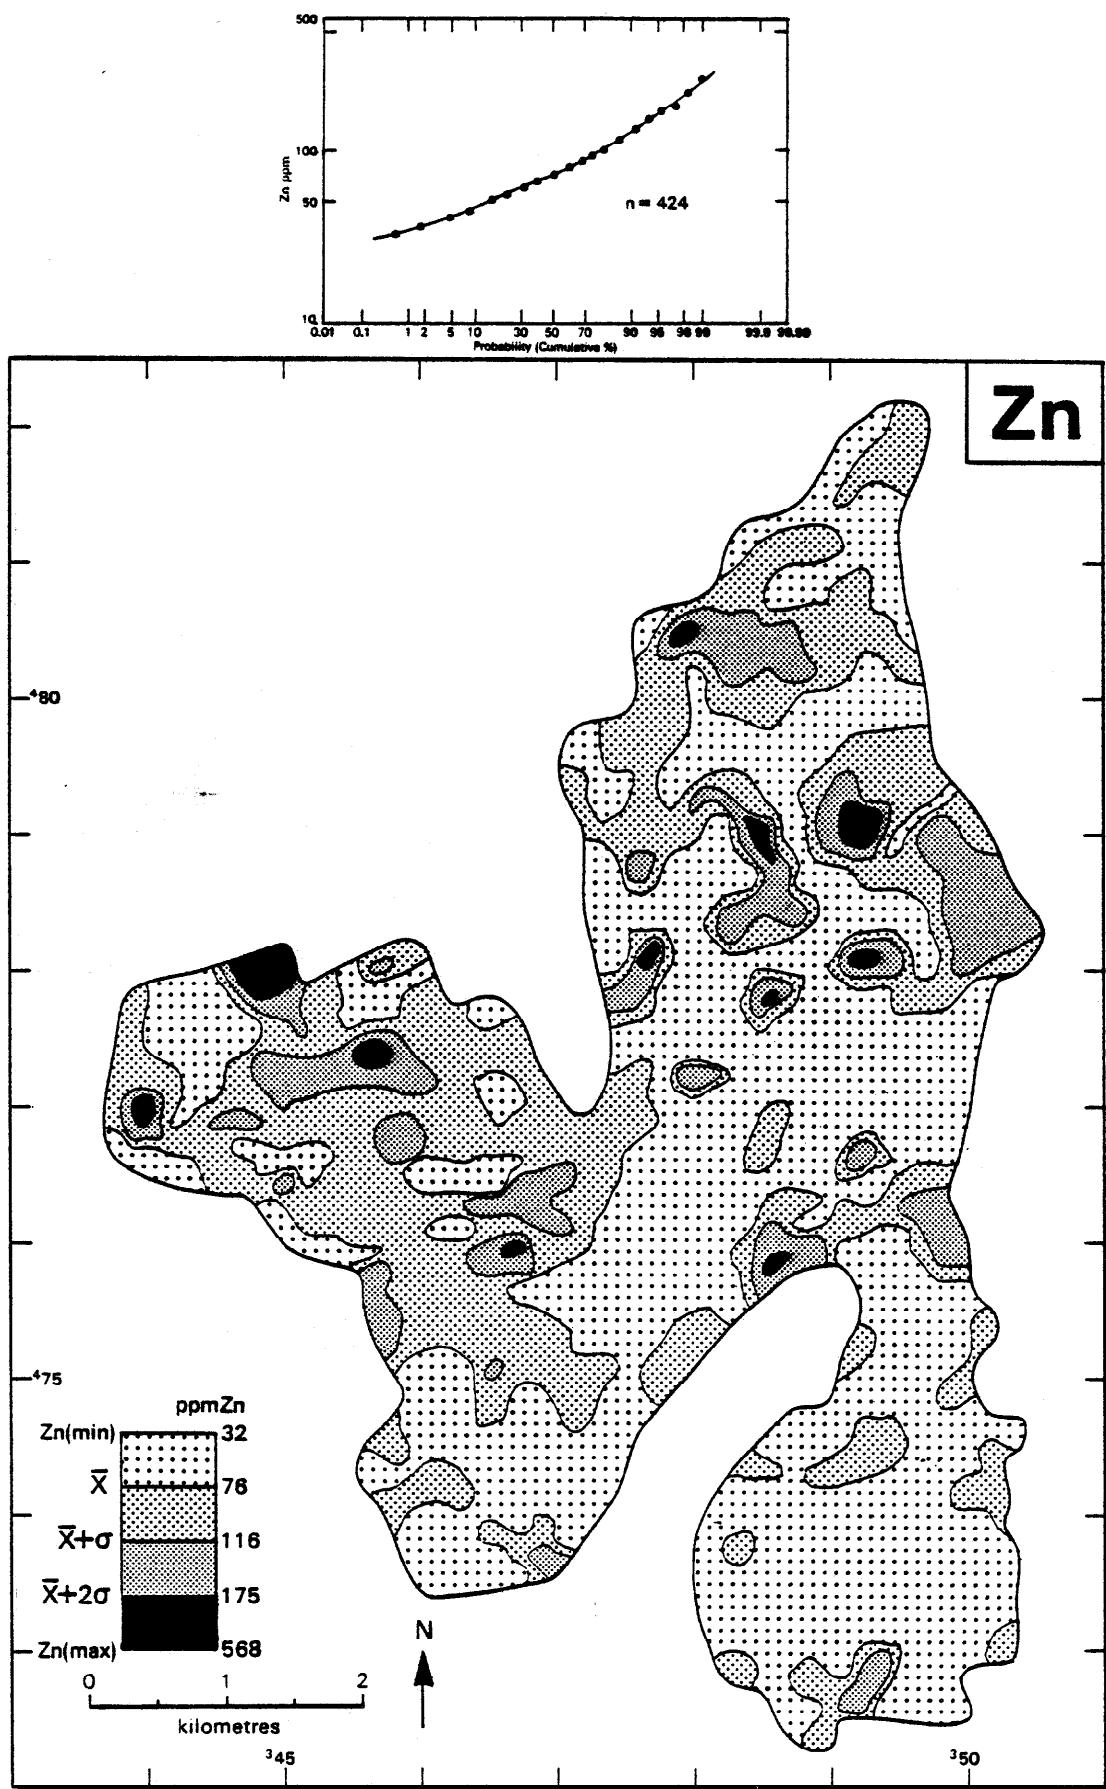

Figure 23 A distribution map of lead in the soils from Warton Crag, Silverdale, Arnside and Beetham (Area IV).

**Figure 24** A distribution map of zinc in the soils from Warton Crag, Silverdale, Arnside and Beetham (Area IV).

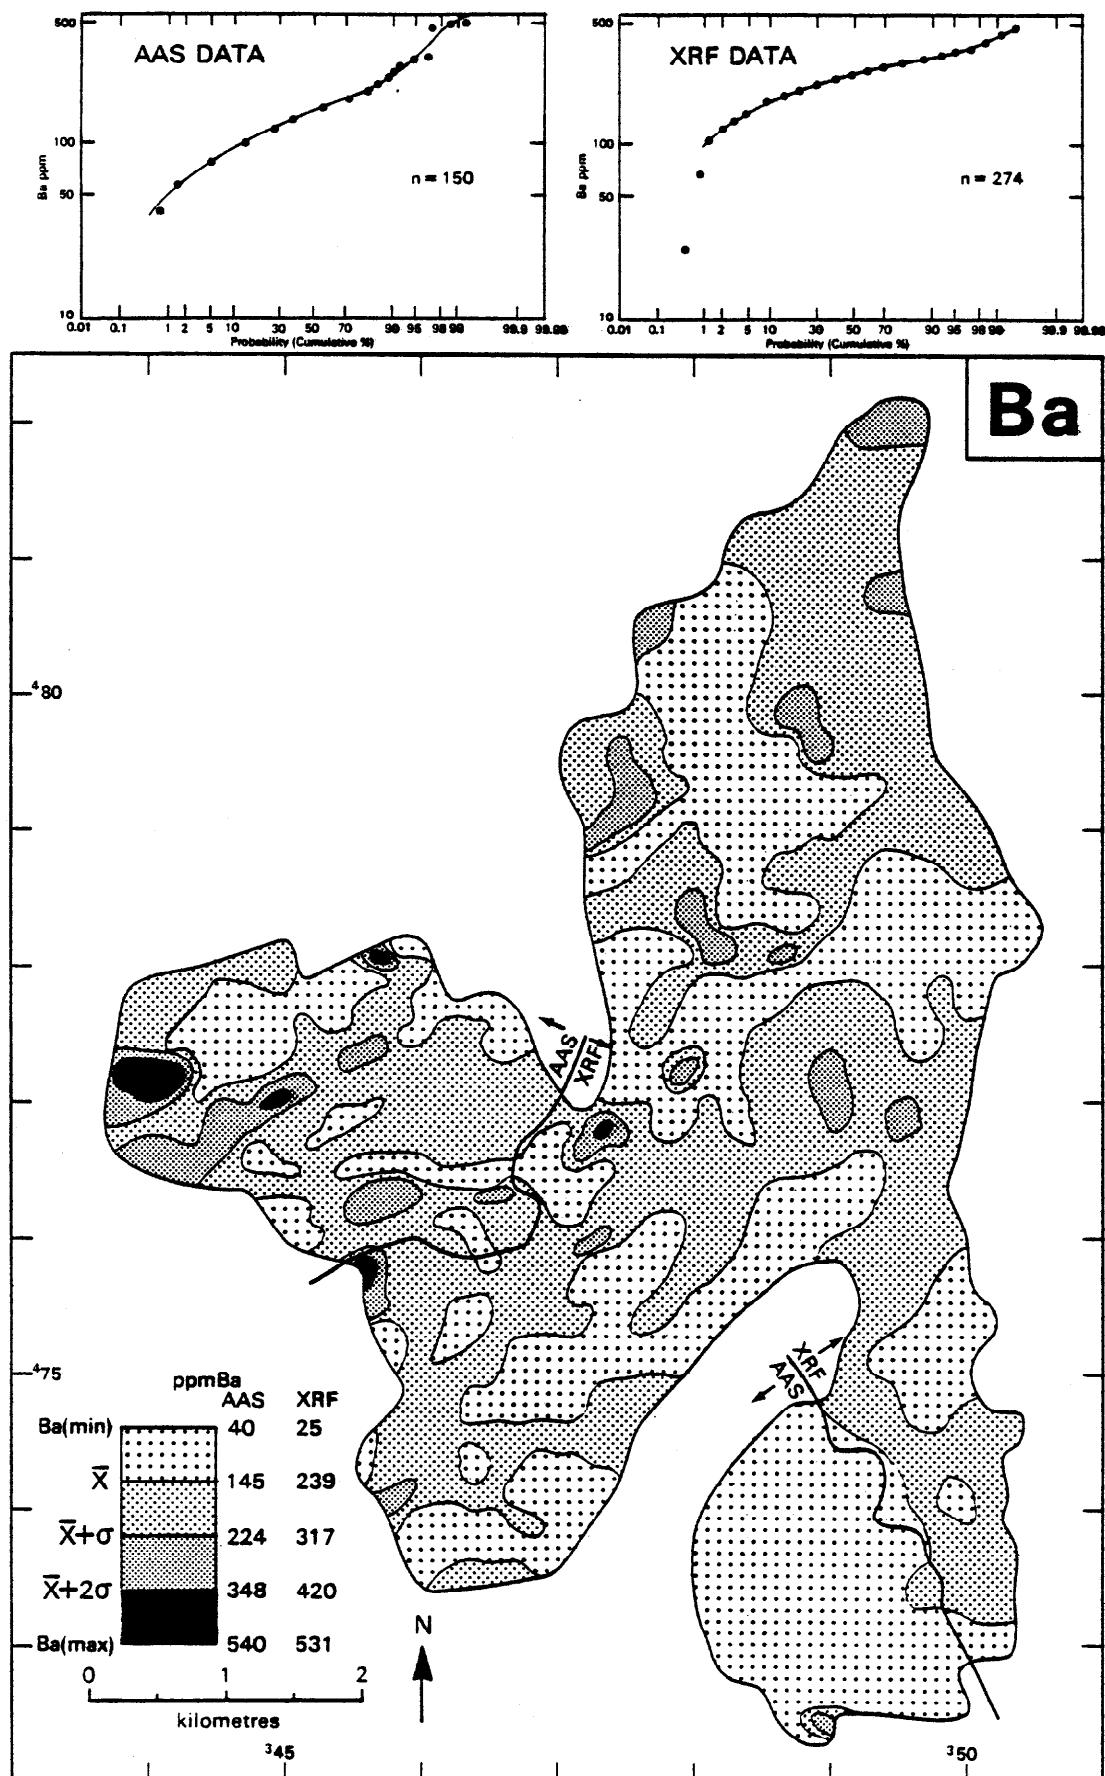

Figure 25 A distribution map of barium in the soils from Warton Crag, Silverdale, Arnside and Beetham (Area IV).

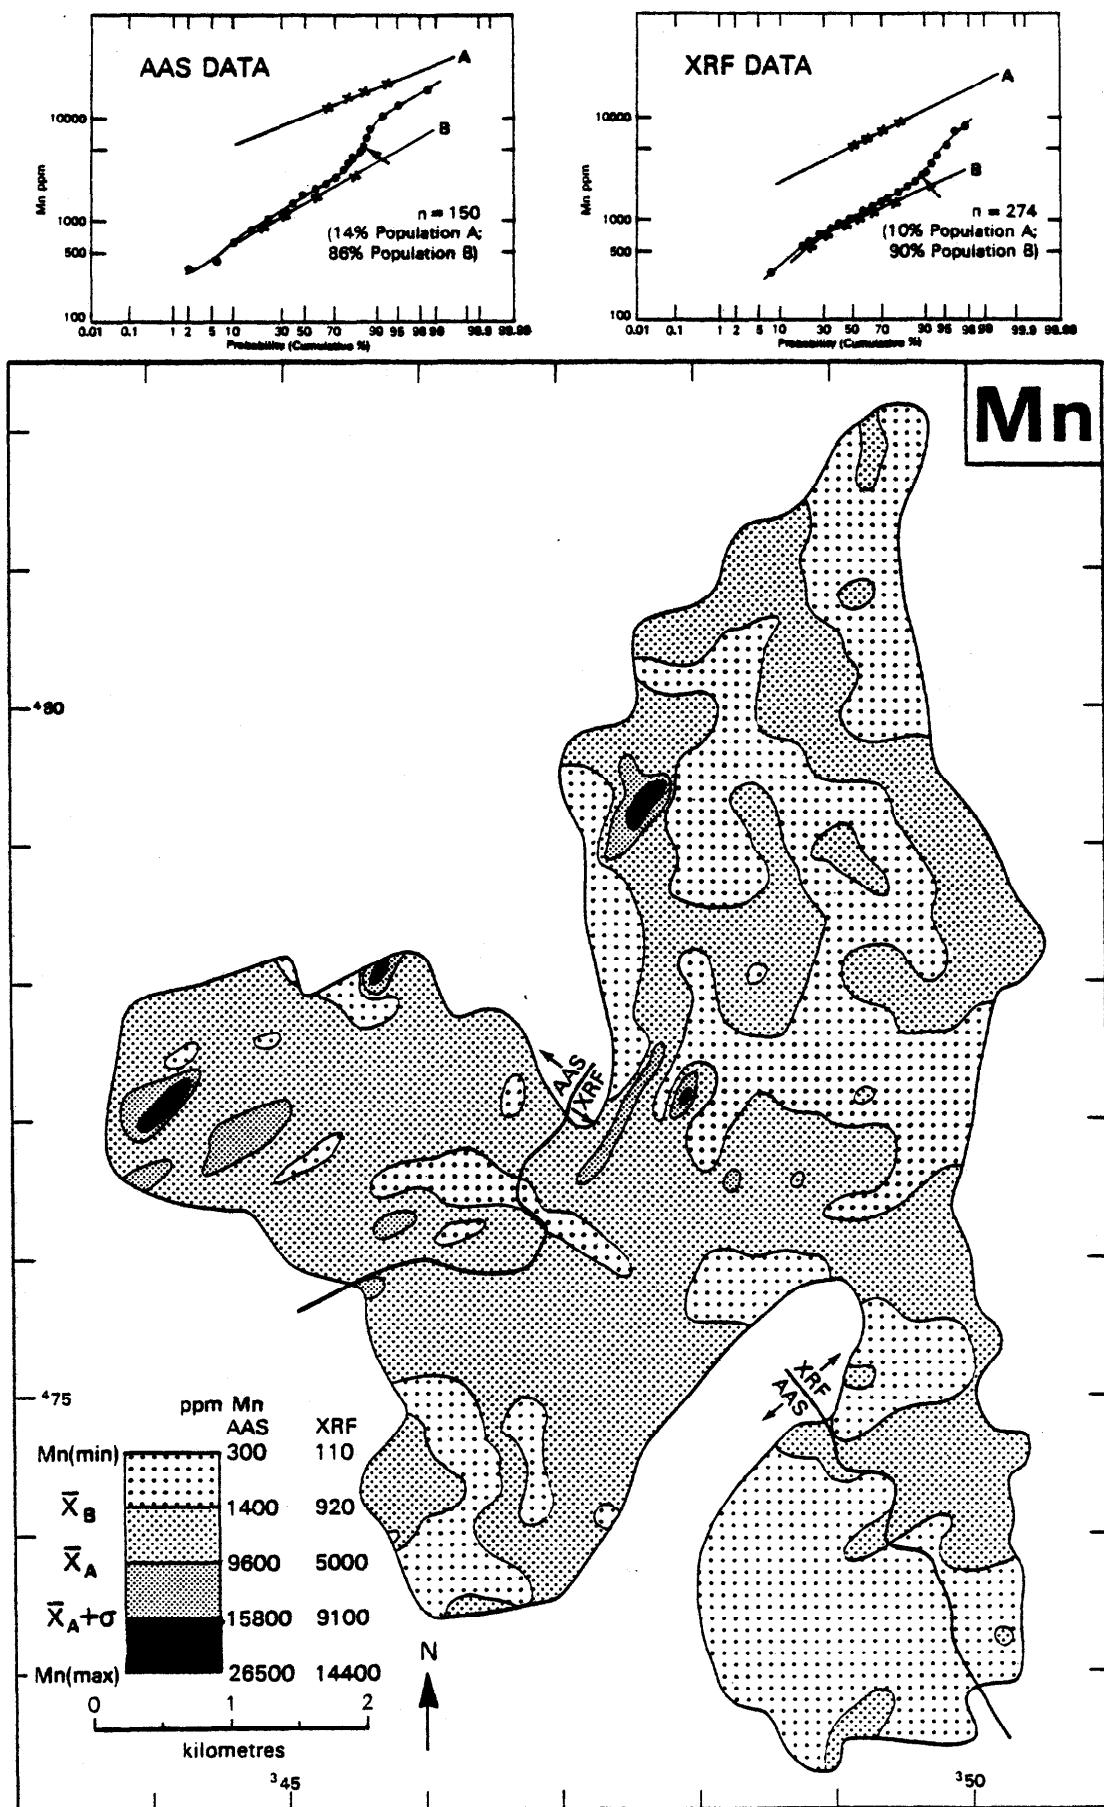

Figure 26 A distribution map of manganese in the soils from Warton Crag, Silverdale, Arnside and Beetham (Area IV).

The anomalies associated with iron workings are probably the result of scavenging the base metals by iron and manganese minerals. None of are significantly high and they cannot be considered worthy of further work.

#### ACKNOWLEDGEMENTS

Messrs M. McGlashan, G. Hewson and R. Matthews collected most of the soil samples. The figures were drawn by the Drawing Office, BGS Keyworth, and the text prepared and formatted by Ms L. K. Waterhouse, Editorial and Publication Unit, BGS Keyworth.
