# Mydrological summary for the United Kingdom <br> <br> General 

 <br> <br> General}

The autumn and early of winter of 2000/2001 is set to join March 1947 and the 1976 drought as major UK hydrological benchmarks - the impact of which have imprinted themselves on a generation. January rainfall totals were generally low in northern regions but again above average in the South-East. With most catchments remaining close to saturation, the flood risk was high throughout the month - in the English Lowlands especially. Exceptional January flows in southern rivers contributed to new maximum three and four-month runoff totals in many areas. Floodplain inundations were less extensive than in late- 2000 but the groundwater dimension to the flood threat assumed a rare prominence. Rising watertables intersected the surface - in the chalk downlands especially - producing 'clear-water' flooding in many localities. Road and basement flooding (and sewer surcharging) were common even in areas with no recent history of such occurrences. Waterlogged land continued to create problems for the farming community and erosion rates remained high. Reservoirs stocks are mostly very close to capacity but freezing conditions in western Scotland, and subsequent pipe-bursts, led to local water supply difficulties.

## Rainfall

The westward extension of a European high pressure cell produced a sunny, cold and more settled month over much of the UK. Dry spells were especially prolonged in the north despite significant snowfall. Outside of the extreme South West and the South East of England, rainfall totals were below the 1961-90 average. North of Loch Ness, totals fell well below $50 \%$; on the eastern seaboard some single figures were recorded. East of Lough Neagh in Northern Ireland, the Midland Valley of Scotland, the Solway Firth and the eastern Peak District experienced percentage totals in the low 40s and below. By contrast, parts of Kent and Hampshire reported their fifth successive month with significantly above average rainfall. A legacy of the remarkably wet autumn and early winter is that long term rainfall accumulations are outstanding. The provisional Sept-Jan rainfall total for the Thames basin is the highest for any fivemonth sequence in a series from 1883. For England and Wales, rainfall over the same period has been around $50 \%$ above average; only in 1960/61 have higher 5-month accumulations (for any start month) been recorded since 1877. For most lowland catchments, and many others in England and Wales, the 5-month rainfall totals, are unprecedented over the period for which the great majority of gauging stations (and observation boreholes) have been in operation. By early February, the area of the South-East which has received around its average annual rainfall (or more) since the beginning of September 2000 had increased appreciably - the Southern region as a whole is just 40 mm short of its annual figure.

## River Flow

Protracted recessions characterised many rivers in western and northern regions of the UK during January. Frozen catchments in northern Scotland yielded particularly modest runoff - the provisional January mean flows for the Rivers Naver and Carron were the second lowest in 20 years. In the English Lowlands, however, a combination of heavy frontal rainfall, saturated soils and continuing high baseflow contribution made for another month of sustained spates. Many rivers exceeded bankfull early in the month (a response to notable rainfall over the four days from Dec $30^{\text {th }}$ )
and many further flood alerts were triggered in the last week of the month. Whilst flows declined in northern Britain, runoff continued to increase in the upper reaches of many spring-fed southern streams as water-tables rose in lagged response to the exceptional recharge of the last four months. In lowland England, new January maximum mean flows were common and the very singular nature of the recent runoff episode is underlined by the 3 - and 4month totals. November-January runoff totals have eclipsed previous maxima by wide margins and exceed $250 \%$ of average in many southern catchments (e.g. the Coln, Mole and Lee). For some, including the Trent, Leven and Dorset Stour and Piddle, the 3-month totals are unsurpassed for any start month. More remarkably, there is no precedent for runoff of this magnitude in the Thames and only one on the Lee (in 1919) in their long flow records from 1883.

## Groundwater

Whilst much of the country has been wet since the early autumn, the greatest rainfall anomalies broadly coincide with the aquifer outcrop areas, the Chalk especially. The relation between rainfall and recharge is non-linear and an increase of $50 \%-80 \%$ in rainfall over the winter halfyear can treble the recharge to eastern aquifer units. Unsurprisingly therefore, recharge since September has been without recorded precedent in many areas. Some modest falls in groundwater levels from the remarkable December peaks were reported (e.g. at Alstonfield and West Woodyates) but, generally, levels continued to rise. Many new absolute maxima were established during January, for example in the Permo-Triassic sandstones (e.g. Heathlanes and Nuttalls Farm), the Magnesian Limestone (Peggy Ellerton), the Upper Greensand (Lime Kiln Way) and the Chalk (Stonor ). Overflowing wells and boreholes were commonplace (e.g. on the South Downs and Salisbury Plain) and outflows from high level springs have been truly exceptional. Whilst 'clear-water' flooding was a feature of established channels, the extension of the drainage network high into 'dry' chalk valleys has often yielded turbid waters accompanying erosion.

February 2000 - January 2001

## Rainfall accumulation maps

Provisionally, September 2000 to January 2001 was the fifth wettest 5 month period (any start month) in the England and Wales rainfall series from 1766. Both the GB and UK series reveal that the last 5 months were the wettest Sep-Jan periods in records since 1877 and from 1900 respectively.

## River flow . . . River flow

## River flows - January 2001

*Comparisons based on percentage flows alone can be misleading. A given percentage flow can represent extreme drought conditions in permeable catchments where flow patterns are relatively stable but be well within the normal range in impermeable catchments where the natural variation in flows is much greater. Note: the period of record on which these percentages are based varies from station to station.

## River flow . . . River flow

## Monthly river flow hydrographs

The river flow hydrographs show the monthly mean flow (bold trace), the long term average monthly flow (dotted trace) and the maximum and minimum flow prior to 1998 (shown by the shaded areas). Monthly flows falling outside the maximum/minimum range are indicated where the bold trace enters the shaded areas.

## Groundwater

## Groundwater

Groundwater levels normally rise and fall with the seasons, reaching a peak in the spring following replenishment through the winter (when evaporation losses are low and soil moist). They decline through the summer and early autumn. This seasonal variation is much reduced when the aquifer is confined below overlying impermeable strata. The monthly max., min. and mean levels are displayed in a similar style to the river flow hydrographs. Note that most groundwater levels are not measured continuously - the latest recorded levels are listed overleaf.

Note. Due to the impact of abstraction on groundwater levels at The Holt borehole, it has been replaced as an index site by the Stonor Park well.

Levels in metres above Ordnance Datum

## Groundwater . . . Groundwater

## Groundwater levels - January 200 I

The rankings are based on a comparison between the average level in the featured month (but often only single readings are available) and the average level in each corresponding month on record. They need to be interpreted with caution especially when groundwater levels are changing rapidly or when comparing wells with very different periods of record. Rankings may be omitted where they are considered misleading.

# National Hydrological Monitoring Programme 

The National Hydrological Monitoring Programme was instigated in 1988 and is undertaken jointly by the Centre for Ecology and Hydrology, Wallingford (formerly the Institute of Hydrology - IH) and the British Geological Survey (BGS). Financial support for the production of the monthly Hydrological Summaries is provided by the Department of the Environment, Transport and the Regions, the Environment Agency (EA), the Scottish Environment Protection Agency (SEPA), the Rivers Agency (RA) in Northern Ireland, and the Office of Water Services (OFWAT).

## Data Sources

River flow and groundwater level data are provided by the regional divisions of the EA (England and Wales) and SEPA (Scotland), data for Northern Ireland are provided by the Rivers Agency and the Department of the Environment (NI). In all cases the data are subject to revision following validation (flood and drought data in particular may be subject to significant revision).

Reservoir level information is provided by the Water Service Companies, the EA, the West of Scotland and East of Scotland Water Authorities, and the Northern Ireland Water Service.

The National River Flow Archive (maintained by CEH Wallingford) and the National Groundwater Level Archive (maintained by BGS) provide the historical perspective within which to examine contemporary hydrological conditions.

## Rainfall

Most rainfall data are provided by The Met. Office (address opposite). To allow better spatial differentiation the rainfall data for Britain are presented for the regional divisions of the precursor organisations of the EA and SEPA. Following the discontinuation of The Met. Office's CARP system in July 1998, the areal rainfall figures have been derived using several procedures, including initial estimates based on MORECS*. Recent figures have been produced by The Met. Office, National Climate Information Centre (NCIC), using a technique similar to CARP. An initiative is underway with The Met. Office to provide more accurate areal figures and, since October 1999, to include more raingauges in the analysis. A significant number of additional monthly rainfall totals are currently being provided by the Environment Agencies; over the coming months further monthly
raingauge totals will be included for selected regions. Until the access to these additional data has stabilised the regional figures (and the return periods associated with them) should be regarded as a guide only.
*MORECS is the generic name for the Meteorological Office services involving the routine calculation of evaporation and soil moisture throughout Great Britain.

The National Hydrological Monitoring Programme depends on the active cooperation of many data suppliers. This cooperation is gratefully acknowledged; the Hydrological Summaries for the autumn and early winter of 2000/2001, in particular, stand as a testimony to the assistance provided by many hydrometric personnel working in exceptionally challenging circumstances.

## Subscription

Subscription to the Hydrological Summaries costs $£ 48$ per year. Orders should be addressed to:

[^0]:    The monthly rainfall figures* are copyright of The Met. Office and may not be passed on to any unauthorised person or organisation. All monthly totals since December 1998 are provisional (see page 12). The return period estimates are based on tables provided by the Meteorological Office (see Tabony, R.C., 1977, The variability of long duration rainfall over Great Britain, Scientific Paper No. 37) and relate to the specified span of months only (return periods may be up to an order of magnitude less if $n$-month periods beginning in any month are considered); RP estimates for Northern Ireland are based on the tables for north-west England. The tables reflect rainfall over the period 1911-70 and assume a stable climate. Artifacts in the England \& Wales and Scotland rainfall series can exaggerate the relative wetness of the recent past. "See page 12 .

[^1]:    Details of the individual reservoirs in each of the groupings listed above are available on request. The featured reservoirs may not be representative of the storage conditions across each region; this can be particularly important during droughts. The minimum storage figures relate to the 1988-2000 period only (except for West of Scotland where data commence in 1994). In some gravity-fed reservoirs (e.g. Clywedog) stocks are kept below capacity during the winter to provide scope for flood attenuation purposes.
