7

8 Running Title: Ozone reduces the yield of African crops

9

10 Abstract

11 Northern, Southern and Equatorial Africa have been identified as among the regions  
12 most at risk from very high ozone concentrations. Whereas we know that many crop  
13 cultivars from Europe, north America and Asia are sensitive to ozone, almost nothing  
14 is known about the sensitivity of staple food crops in Africa to the pollutant. In this  
15 study cultivars of the African staple food crops *Triticum aestivum* (wheat), *Eleusine*  
16 *coracana* (finger millet), *Pennisetum glaucum* (pearl millet) and *Phaseolus vulgaris*  
17 (bean) were exposed to an episodic ozone regime in solardomes in order to assess  
18 whether African crops are sensitive to ozone pollution. Extensive visible leaf-injury  
19 due to ozone was shown for many cultivars, indicating high sensitivity to ozone.  
20 Reductions in total yield and 1000-grain weight were found for *T. aestivum* and *P.*  
21 *vulgaris*, whereas there was no effect on yield for *E. coracana* and *P. glaucum*. There  
22 were differences in sensitivity to ozone for different cultivars of an individual crop,  
23 indicating that there could be possibilities for either cultivar selection or selective crop  
24 breeding to reduce sensitivity of these crops to ozone.

25

26 Keywords

27 Millet, wheat, bean, 1000-grain weight, visible leaf-injury, photosynthesis

28 1 Introduction

29 1.1 Tropospheric ozone as a global pollutant

30 Ozone is a major air pollutant at ground-level and is formed when precursor molecules  
31 including NO<sub>x</sub> and VOC's (volatile organic compounds) react in the presence of  
32 sunlight. Tropospheric ozone concentrations vary spatially and tend to be highest in  
33 parts of the USA, southern Europe, southern Asia and equatorial Africa (Cooper et al.,  
34 2014; Dentener et al., 2006; Stevenson et al., 2006). Trends in tropospheric ozone  
35 concentrations vary geographically. Although there is very little measured data on  
36 ozone concentration trends in Africa, ozone concentrations in many regions of Asia  
37 have been increasing over recent years. For example, most of the regions of India  
38 have been increasing over the period 2005-2010 and this is consistent with reported  
39 trends in coal and petroleum consumption (Lal et al., 2012). Ozone concentrations  
40 have also been increasing over the last 10 years in South Korea (Shin et al., 2017) and  
41 in many regions of China, including the Yangtze River Delta (Wang et al., 2018) and  
42 are projected to increase further in many regions of Asia (Ma et al., 2016, Sun et al.,  
43 2016, Xu et al., 2016).

44

45 In Kenya and other countries of Africa, coal and petroleum consumption are also  
46 increasing rapidly, due in part to increased vehicle use, and ozone precursor emissions  
47 are anticipated to increase further due to NO release from soils as additional N is added  
48 to increase crop yield (Hickman et al., 2017). Northern and Southern Africa have been  
49 identified as among the regions most at risk from very high ozone concentrations under  
50 a 'policy fail' SRES A2-type emissions scenario (Royal Society, 2008; Laban et al.,

51 2018) unless measures are taken to reduce precursor emissions (Wild et al., 2012).  
52 One of the sources of precursors is biomass burning, and regions of tropical biomass  
53 burning have elevated ozone compared to the rest of the tropics (Anderson et al.,  
54 2016). Evidence from India has shown that air masses originating from areas of crop  
55 residue burning on the Indo-Gangentic Plain can enhance ozone concentrations  
56 downwind by up to 32 ppb (Kumari et al., 2018). Similarly, the ozone concentrations  
57 in Rwanda during the dry season are increased by transport of precursors during  
58 biomass burning in northern and southern Africa (DeWitt et al., 2019). Ozone  
59 concentrations are projected to rise further in many developing regions, including  
60 Africa (Huang et al., 2018). In addition to anticipated changes in precursor emissions,  
61 African regions are also predicted to have an increase in surface mean ozone  
62 concentrations due to projected changes in climate (Racherla and Adams, 2006).

63

64 Although other air pollutants are also present in tropical regions, including fine  
65 particles  $PM_{2.5}$  (Brauer et al., 2012), ozone concentrations are increasing rapidly and  
66 there is less potential to control concentrations locally than for some other pollutants  
67 such as  $PM_{2.5}$  due to the hemispherical transport of ozone precursors. Although there  
68 is some sporadic monitoring of air pollutants including ozone in some parts of Africa,  
69 particularly in south Africa (Laban et al., 2018), there is currently very little  
70 monitoring of ambient ozone concentrations across most of Africa (Schultz et al.,  
71 2017) and where data is available time series are often short. Reported values often  
72 tend to be as 24 hour mean values, which may not be representative of daytime mean  
73 concentrations when plants are active, and these daytime concentrations would be  
74 expected to be much higher than those during the night due to the diurnal profile of  
75 ozone concentrations observed in urban areas e.g. Hanoi (Sakamoto et al., 2018).

76 Values presented may also be from urban monitoring stations (e.g. from Nairobi city,  
77 Kimayu et al., 2017), where concentrations would be anticipated to be lower than for  
78 rural regions due to scavenging in the urban environment by titration with NO.  
79 Similarly, in China it has been shown that a rural area 100km downwind of Beijing  
80 had ozone concentrations much higher than in the city, with mean values of 58 ppb in  
81 the rural area compared to 36 ppb in Beijing city (Xu et al., 2011), and a maximum  
82 value of 198 ppb. Thus, air pollution is a relevant problem for rural and agricultural  
83 areas in developing countries in addition to the more well-known air pollution  
84 problems within cities.

85

## 86 1.2 Differential sensitivity of plants to ozone pollution

87 Ozone enters plants through stomatal pores on the leaf surfaces and once inside the  
88 leaf can react with plant surfaces to form reactive oxygen species (Wilkinson et al.,  
89 2012). These can damage cell membranes and structures within the apoplast and cause  
90 a cascade of biochemical reactions that can damage photosynthetic apparatus  
91 (Caregnato et al., 2013) and ultimately lead to cell death and promote premature leaf  
92 senescence (Fiscus et al., 2005; Schraudner et al., 1997). Some crops and cultivars are  
93 much more sensitive to ozone than others (Mills et al., 2007). Reasons for differential  
94 sensitivity include the ability to exclude ozone by stomatal regulation (Hoshika et al.,  
95 2013; Salvatori et al., 2013), the rate of induction of detoxification of reactive oxygen  
96 species (ROS) to protect photosynthetic apparatus (Di Baccio et al., 2008) and the  
97 plasticity of resource partitioning to replace damaged leaves (Grantz et al., 2006).  
98 However, we do not yet know about the sensitivity of African crops.

99

### 100 1.3 Impact of ozone on crop yields

101 Food supply for a rising global population is one of the priorities for the 21<sup>st</sup> century,  
102 with agricultural productivity being one of the contributing factors (e.g United Nations  
103 Sustainable Development Goal 2, UN General Assembly, 2015). Many crops have  
104 been shown to be sensitive to ozone pollution, including staple foods such as rice  
105 (Akhtar et al., 2010), wheat (Wahid, 2006) and soybean (Betzberger et al., 2012).  
106 Analysis of compiled datasets from many experiments has shown a wide range in  
107 ozone-sensitivity between different crops, based on ozone concentration (Mills et al.,  
108 2007, 2018a; Mills and Harmens, 2011). Model-based studies using dose-response  
109 functions from such datasets have indicated potential crop yield reductions due to  
110 ozone across wide regions of the world (Mills et al, 2018a,b,c; Van Dingenen et al.,  
111 2009, Avnery et al., 2011). Experimental investigations have shown impacts of  
112 ambient ozone concentrations on a wide range of crop species in Europe and the USA  
113 by comparing responses of plants in filtered air to those in non-filtered air (Pleijel et  
114 al, 2018; Marzuoli et al., 2017; De Temmerman et al, 2007). However, the majority  
115 of current information on crop sensitivity to ozone is based on studies from Europe  
116 and the USA, with some additional more recent studies in India and China (Tomer et  
117 al., 2015; Chen et al, 2008; Singh and Agrawal, 2017; Feng et al., 2017; Feng et al.,  
118 2015). There is very little information on responses to ozone of tropical crop species,  
119 particularly those relied on by subsistence farmers, such as pearl and finger millet.

120 Sub-Saharan Africa continues to have the highest proportion of individuals that are  
121 undernourished in terms of food quantity and nutrition and no information currently  
122 exists on the sensitivity to ozone for some of the Sub-Saharan African major crop  
123 species.

124

#### 125 1.4 Inter-continental variations in ozone sensitivity

126 It has been shown that ozone sensitivity of soybean cultivars has increased  
127 progressively over time, and it was suggested that this was due to selective breeding  
128 strategies for increased stomatal conductance and yield, which may have inadvertently  
129 selected for greater ozone sensitivity (Osborne et al., 2016). Similarly for wheat, it has  
130 been shown that the stomatal conductance of cultivars has increased over time, and  
131 this also correlates to an increase in sensitivity to ozone (Biswas et al., 2008), although  
132 in the case of wheat this conclusion has largely been based on comparisons between  
133 old and modern cultivars (e.g. Pleijel et al., 2006). However, there is also some  
134 evidence of different sensitivity of cultivars of a single crop type used in different  
135 continents, which might be due to differing selection criteria in different locations,  
136 perhaps due to requirements for suitability in a particular climate. Soybean cultivars  
137 from India and China were more sensitive to ozone than those from Europe and the  
138 USA (Osborne et al, 2016). A greater sensitivity of Asian cultivars of wheat and rice  
139 compared to USA cultivars has also been shown (Emberson et al., 2009). This may be  
140 due to differences in breeding strategies between different regions, although it was  
141 recognised that other factors such as experimental methodology and co-occurring  
142 pollutants may also be part of the explanation, in addition to differential cultivar  
143 sensitivity.

144

#### 145 1.5 Aims and rationale for selection of crops and cultivars

146 In Africa, the staple foods vary by region and include wheat and millet, which had a  
147 total African production of 23 065 000 Tonnes and 13 642 000 Tonnes respectively in  
148 2016 (FAOstat). Dry beans (*Phaseolus vulgaris*) are mainly grown for subsistence and  
149 provide a major component of dietary protein (FAO.org; Broughton et al., 2003), with

150 an African production of 6 789 000 Tonnes in 2016 (FAOstat). There are over 40 000  
151 varieties of bean, including indigenous, unimproved landraces and improved modern  
152 cultivars (Graham and Ranalli, 1997).

153

154 The aim of this study was to evaluate ozone sensitivity of a range of food crops grown  
155 in tropical regions in Africa. This information will be used to indicate whether ozone  
156 is likely to be a problem for crops in sub-Saharan Africa and similar regions. Several  
157 varieties of each crop were tested to determine whether there is scope for selecting  
158 cultivars with reduced ozone sensitivity, thereby preventing or limiting yield losses  
159 due to the pollutant.

160

## 161 2 Methods

### 162 2.1 Seeds and planting

163 *Triticum aestivum* (wheat) seeds of the Kenyan cultivars ‘Kenya Korongo’, ‘Kenya  
164 Wren’, ‘Kenya Hawk 12’, ‘Eagle 10’, ‘Njoro BWII’ were obtained from the Kenya  
165 Agriculture and Livestock Research Organisation (KALRO; Njoro-Kenya). *Triticum*  
166 *aestivum* seeds of the UK cultivar ‘Skyfall’ were obtained from RAGT Seeds (UK) to  
167 compare the sensitivity of the Kenyan cultivars with an ozone-sensitive cultivar of the  
168 UK (Harmens et al., 2018). *Eleusine coracana* (finger millet) of cultivars GuluE,  
169 P224, KNE624, KNE814, U15, Okhale, and *Pennisetum glaucum* (pearl millet) of  
170 cultivars Okashana, Shibe, ICMV221, KATPM1 were obtained from the International  
171 Crops Research Institute for the Semi-Arid Tropics (ICRISAT-Nairobi, Kenya).  
172 *Phaseolus vulgaris* (bean) of the widely grown cultivars ‘Black Turtle’, ‘Pinto’ ‘Orca’  
173 (syn ‘Ying Yang’) and ‘Cannellini’ were obtained from Jungle Seeds Ltd, UK.

174

175 Cereal crops were planted in 6.5 l pots (diameter 21 cm, height 25 cm), and beans were  
176 planted in 7.5 l pots (diameter 26 cm, height 21 cm). All pots were filled with John  
177 Innes No 3 soil based compost (J. Arthur Bowers, UK), which contains loam soil and  
178 added nutrients, to prevent possible confounding impacts of growing in sub-optimal  
179 soil conditions. Seeds were sown on 28<sup>th</sup> April 2017 and seedlings were thinned to 9  
180 per pot (*T. aestivum*), 4 per pot (*E. coracana*), 2 per pot (*P. glaucum*) and 1 per pot (*P.*  
181 *vulgaris*). Four replicate pots were used per cultivar per ozone treatment, and all plants  
182 were in the vegetative stage when ozone exposure started. Due to the differences in  
183 required growing conditions, *T. aestivum* was grown and exposed to ozone in unheated  
184 solardomes, whereas for the other crops, heated solardomes were used with an increase  
185 in temperature of approximately 7 °C above ambient (discussed in section 2.2). A  
186 summary of key dates and details of treatments is shown in Table 1. Note that the  
187 ozone exposure time was much shorter for *P. glaucum* than for the other crops, as this  
188 grew too tall to fit in the solardomes. All plants were kept well-watered for the duration  
189 of the experiment.

190

## 191 2.2 Ozone system

192 Plants were exposed to ozone in solardomes – hemispherical glasshouses (3m  
193 diameter, 2.1m high) at Abergwyngregyn, near Bangor, North Wales, UK. The  
194 solardomes were ventilated at a rate of two air changes per minute. Ozone was  
195 generated using an ozone generator (G11, Ozone Industries Ltd), supplied by an  
196 oxygen concentrator (Sequal 10, Pure O<sub>2</sub>). Charcoal filtered air was injected with  
197 ozone to give required concentrations using solenoid valves operating using pulse-  
198 width modulation. Concentrations were computer controlled using LabView (Version  
199 2012, National Instruments, Texas, USA) and followed an episodic ozone regime

200 (with five consecutive 'high' days in every 7-day week), to represent a profile that  
201 might be experienced in agricultural areas of Sub-Saharan Africa, based on profiles  
202 that were experienced in Mediterranean Europe in the 1990's and 2000's (Figure 1).  
203 The ozone concentration inside each solardome was measured for 5 minutes every 30  
204 minutes using two ozone analysers (Envirotech, UK; 49i Thermo Scientific, UK) of  
205 matched calibration.

206

207 Heating was achieved using air conditioning units (Toshiba Super Digital Inverter,  
208 Toshiba-Aircon, UK) that were electronically controlled (Easy I/O, The  
209 Netherlands). The temperature regime used was to represent that of African  
210 countries such as Kenya, which has daily mean temperature between 20-28°C. Crops  
211 such as millets and beans tend to be grown in the warmer regions and wheat tends to  
212 be grown in higher altitude, cooler regions. In one ambient temperature solardome  
213 and three heated solardomes, temperature and relative humidity were continuously  
214 measured (Skye Instruments, UK) and in one ambient temperature solardome  
215 Photosynthetically Active Radiation (PAR) was also continuously monitored (Skye  
216 Instruments, UK). Climatic conditions and airflow rates were matched between  
217 solardomes, however, to minimise any chamber effects all plants and ozone  
218 treatments were moved between solardomes every four weeks. Ozone concentrations  
219 and climatic conditions of the treatments are shown in Table 2, and further details of  
220 ozone exposure to individual cultivars is given in the Supplementary Information.

221

### 222 2.3 Leaf injury assessments

223 Visible leaf injury assessments of all plants was carried out after 2 weeks by counting  
224 all leaves per plant and categorising each leaf as 'healthy', 'mild' ozone injury (<5%

225 of the leaf affected, based on visual assessment), ‘moderate’ ozone injury (5%-25%  
226 of the leaf affected) or ‘severe’ ozone injury (>25% of the leaf affected).

227

#### 228 2.4 Plant physiological measurements

229 Light-saturated rate of net photosynthesis ( $A_{\text{sat}}$ ) and stomatal conductance for water  
230 vapour ( $g_s$ ) were measured simultaneously using a portable infrared gas analyser (LI-  
231 6400XT, LI-COR, Nebraska, USA). Measurements for *T. aestivum* were made on the  
232 flag leaf. Measurements for *P. glaucum* and *E. coracana* were made on typical leaves  
233 from the upper canopy. For *P. vulgaris* in the medium and high ozone treatments,  
234 many leaves initially showed symptoms of ozone damage, then quickly senesced.  
235 Therefore, for *P. vulgaris* measurements were made on healthy leaves of the upper  
236 canopy. All measurements were between the times of 10:00 and 16:30 and used a LED  
237 light attached to the leaf cuvette, set at photosynthetic photon flux density of 1500  
238  $\mu\text{mol m}^{-2} \text{s}^{-1}$ . The  $\text{CO}_2$  concentration of the air entering the leaf cuvette was set at 400  
239 ppm, and the leaf temperature was regulated at 20°C for *T. aestivum* and 35 °C for *P.*  
240 *glaucum*, *E. coracana* and *P. vulgaris*, to reflect the temperature within the solardomes  
241 on the measurement days for these plants. Dates of these measurements are indicated  
242 in Table 1, with typically 32 measurements in total per day.

243

244 Additional stomatal conductance measurements were made to establish maximal  
245 stomatal conductance,  $g_{\text{max}}$ , for each species using a porometer (AP4, Delta-T  
246 Devices, Cambridge, UK). A minimum of 100 measurements were made per variety,  
247 and  $g_{\text{max}}$  was determined as the 95<sup>th</sup> centile of the measured values. Stomatal  
248 conductance for ozone was calculated using the conversion factor of 0.663 to account  
249 for the difference in the molecular diffusivity in air of water vapour to that of ozone

250 (Massman, 1998). This was then expressed in terms of projected leaf area (PLA) using  
251 measured proportion of stomatal conductance from the abaxial surface as 0.8, 0.5, 0.7  
252 and 0.5 for *T. aestivum*, *E. coracana*, *P. glaucum* and *P. vulgaris* respectively. For all  
253 measured leaves, chlorophyll content was determined using a hand-held chlorophyll  
254 meter (CCM200plus; Opti-Sciences, Hudson, USA) recording Chlorophyll Content  
255 Index (CCI).

## 256 2.5 Plant harvest

257 Plants were harvested when seeds were ready. Grains were extracted from *T. aestivum*  
258 ears using a hand-thresher (Minibatt+, Reichhardt Electronic Innovations, Germany).  
259 Grains were extracted by hand for the other crops, although this was only partially  
260 successful for *E. coracana* and *P. glaucum*.

261

## 262 2.6 Statistical methodology

### 263 2.6.1 Leaf Injury

264 To investigate if the number of leaves per injury category varied with ozone treatment,  
265 a multinomial logistic regression model was run using the statistical program R (R  
266 Core Team 2016), with the ‘multinom’ function from the nnet package (Venables &  
267 Ripley 2002; for further detail see Supplementary Information). A categorical  
268 response variable was created from the injury counts, which were performed after two  
269 weeks of ozone exposure. The four categories were 1) Number of leaves with no  
270 injury; 2) Number of leaves with mild injury; 3) Number of leaves with moderate  
271 injury; 4) Number of leaves with severe injury. Predictor variables in the model were  
272 ozone treatment (low, medium, high), and crop cultivar. The optimal model was  
273 chosen using top down selection with examination of Akaike Information Criterion  
274 (AIC) values, following Zuur et al. (2009). This process was repeated using the data

275 for each crop type. Predicted probabilities of the different possible outcomes of the  
276 injury counts were plotted for each crop type. Post-hoc testing was carried out by  
277 comparing the simulated predicted probabilities per cultivar for a chosen level of  
278 damage using paired t-tests.

279

#### 280 2.6.2 Relationship between $A_{\text{sat}}$ , $g_s$ and chlorophyll content index (CCI)

281 Linear mixed-effects models (normal error) were used to investigate the relationships  
282 between  $A_{\text{sat}}$ ,  $g_s$  and CCI, including a random effect of Pot ID and the categorical  
283 predictor ‘Week’ to control for any effects of taking repeat measurements in three  
284 different weeks for each crop species. Firstly, the effect of CCI and ozone on  $A_{\text{sat}}$  was  
285 investigated for each crop, with models including CCI and ozone (plus their  
286 interaction) as predictor variables. For the *T. aestivum* model, CCI was found to  
287 decrease with higher ozone ( $p < 0.001$ ), therefore both predictors were not included  
288 together in the  $A_{\text{sat}}$  model. For the *P. vulgaris* and *P. glaucum* models, CCI was log  
289 transformed as  $A_{\text{sat}}$  values increased then began to level off with higher values of CCI.  
290 Marginal  $R^2$  ( $R^2_M$ ; proportion of variance explained by the fixed effects) was used to  
291 report model fit. The effect of ozone on  $g_s$  was then investigated for each crop,  
292 including an interaction with ‘Week’ in the model set. Lastly, the effect of  $g_s$  on  $A_{\text{sat}}$   
293 was investigated for each crop. For crops showing no effect of ozone on  $g_s$ , models  
294 included both ozone and  $g_s$  (plus their interaction) as predictor variables.

295

#### 296 2.6.3 Yield and 1000-grain/seed weight

297 To investigate the effect of ozone on the total yield and 1000-grain weight, linear  
298 models (normal error) were used, including ozone, crop cultivar and their interaction  
299 as categorical predictors in the model. For *P. vulgaris*, an additional covariate of pot

300 number was included to control for any initial variations in plant size (pots per  
301 treatment were labelled 1-4 based on their starting size). Linear models (with normal  
302 error, after reviewing distribution of model residuals) were also used to determine if  
303 ozone had an effect on the number of ears per pot and the number of grains per ear for  
304 *T. aestivum*. Post-hoc testing was carried out using Tukey's range test  
305 All models were run using R and residuals were examined for normality and even  
306 spread. Data transformations were carried out if necessary. For each model set, top  
307 down model selection was carried out, following Zuur et al., (2009). For the mixed-  
308 effects models (package lme4; Bates et al., 2015), p-values were obtained using  
309 Likelihood Ratio Tests (LRT) with the drop command, and model fitted values were  
310 obtained using the 'predict' function. The R package 'MuMIn' was used to calculate  
311 Marginal R<sup>2</sup> for the optimal mixed models (Barton, 2018).

## 312 3 Results

### 313 3.1 Visible injury

314 All crops and cultivars tested showed visible leaf injury after two weeks of ozone  
315 exposure (Figure 2 and S1). For *T. aestivum*, all cultivars showed similar responses  
316 within each level of ozone, with the probability level of visible injury being present  
317 increasing with increasing ozone (no interaction between ozone and cultivar). At low  
318 ozone, very little visible injury was recorded on *T. aestivum* leaves. *T. aestivum*  
319 cultivars showed a difference in sensitivity to ozone. At high ozone, sensitivity was of  
320 the order 'Skyfall' > 'Korongo' > 'Wren' > 'Njoro' > 'Hawk' > 'Eagle' for moderate  
321 injury. Post-hoc testing for high ozone showed a significant difference between the  
322 predicted probabilities of moderate injury for each cultivar. The two most sensitive  
323 cultivars ('Skyfall' and 'Korongo') also showed the highest probability of severe  
324 injury on leaves at high ozone.

325

326 The *E. coracana* cultivars behaved differently depending on the ozone treatment (the  
327 optimal model contained an interaction between ozone and cultivar). There was no  
328 visible injury present in the low ozone treatment. At medium ozone, there were clear  
329 differences between cultivars. 'GuluE' showed very low ozone sensitivity, while  
330 'P224' and 'U15' were the most sensitive cultivars. At high ozone, all cultivars  
331 behaved similarly and all showed severe injury (although 'GuluE' was still showing a  
332 higher predicted proportion of mild injury than the other cultivars). At high ozone,  
333 sensitivity was of the order 'P224' > 'U15' > 'KNE814' > 'Okhale' > 'KNE624' >  
334 'GuluE' for severe injury. Post-hoc testing for high ozone showed a significant  
335 difference between the predicted probabilities of severe injury for each cultivar.

336

337 In terms of visible injury, *P. glaucum* was less sensitive than *T. aestivum* and *E.*  
338 *coracana*, but some injury was still apparent on all cultivars in both the 'high' and  
339 'medium' ozone treatments. All cultivars showed similar behaviour at each level of  
340 ozone, with the probability level of visible injury being present increasing with  
341 increasing ozone (there was no interaction between ozone and cultivar). None of the  
342 cultivars showed any severe injury, even at high ozone. For *P. glaucum* at high ozone,  
343 sensitivity was of the order 'Okashana' > 'Shibe' > 'ICMV221' > 'KATPM1' for  
344 moderate injury. Post-hoc testing for high ozone showed a significant difference  
345 between the predicted probabilities of moderate injury for each cultivar.

346

347 There was no visible injury present in the low ozone treatment for *P. vulgaris*. The  
348 'Turtle' bean cultivar responded slightly differently to the other bean cultivars, and  
349 data for this cultivar was analysed separately (Figure S2). The extent of visible leaf

350 injury was variable between the different cultivars of *P. vulgaris* in the medium ozone  
351 treatment, and this remained consistent at high ozone (no interaction between ozone  
352 and cultivar) (Figure 2). The most extensive and severe leaf damage was shown for  
353 the 'Pinto' cultivar. Sensitivity to high ozone for *P. vulgaris* was in the order 'Pinto'  
354 > 'Cannellini' > 'Orca' for severe injury, with post-hoc tests showing a significant  
355 difference between the predicted probabilities for each cultivar. Turtle beans showed  
356 a higher predicted probability of severe injury in the medium ozone treatment,  
357 compared to the high ozone treatment (Figure S2).

358

### 359 3.2 Relationship between $A_{\text{sat}}$ , $g_s$ and chlorophyll index

360 For *T. aestivum* there was a tight positive relationship between  $A_{\text{sat}}$  and CCI, which  
361 was linear within the range tested ( $p < 0.001$ , model  $R^2M = 0.89$ ; Figure 3a).  
362 Relationships between  $A_{\text{sat}}$  and CCI showed more scatter in the data for *E. coracana*,  
363 *P. glaucum* and *P. vulgaris* (Figure 3b-d). For *E. coracana* the relationship was also  
364 linear within the range tested ( $p < 0.001$ , model  $R^2M = 0.67$ ), however, for *P. glaucum*  
365 and *P. vulgaris* the relationship was logarithmic, showing some evidence of a plateau  
366 being reached at higher values of CCI and a higher  $R^2$  for the relationship for these  
367 crops when a logarithmic function was used ( $p < 0.001$  for both crops, model  $R^2M =$   
368  $0.44$  and  $0.70$  respectively). For *T. aestivum*, CCI decreased with increasing ozone  
369 (Table S6), over time. After five weeks of ozone exposure, there was no difference in  
370 CCI between treatments, however after six and seven weeks, the CCI was lower in the  
371 high ozone compared to the other ozone treatments (Time \* ozone  $p < 0.001$ ). For the  
372 other crops, there was no significant effect of ozone on the CCI of the measured leaves  
373 ( $p > 0.05$ ) (Table S6).

374

375 The ozone treatment did not affect the slope of the  $A_{\text{sat}}$  vs. chlorophyll relationship for  
376 *E. coracana* or *P. glaucum* ( $p > 0.05$  for ozone \* CCI). This was not tested for *T.*  
377 *aestivum* as the effect of ozone on  $A_{\text{sat}}$  could not be separated from an indirect effect  
378 via reduced chlorophyll. For *P. vulgaris*, model results indicated an interaction  
379 between chlorophyll index and ozone ( $p < 0.001$ ), with a steeper slope and higher  $A_{\text{sat}}$   
380 values for the high ozone treatment. This is thought to be because the high ozone  
381 treatment caused many leaves to senesce prematurely, therefore measurements were  
382 made on healthy, young leaves.

383

384 Stomatal conductance ( $g_s$ ) was significantly reduced with increasing ozone for *T.*  
385 *aestivum* ( $p < 0.001$ ; Table S7). The effect of ozone on  $g_s$  for this species was gradual,  
386 with no difference between low and high treatments on 28<sup>th</sup> June (Week 5), but an  
387 ozone effect recorded on  $g_s$  for subsequent weeks (Time \* ozone,  $p < 0.001$ ,  
388  $R^2M=0.51$ ). There was also an effect of ozone on  $g_s$  for *P. vulgaris* ( $p < 0.001$ ,  
389  $R^2M=0.47$ ), however the highest values of  $g_s$  were recorded in the highest ozone  
390 treatment (Table S7). Again, this is thought to be because healthy leaves were  
391 measured at high ozone for *P. vulgaris*, due to premature leaf drop. There was no  
392 significant effect of ozone on  $g_s$  for *E. coracana* or *P. glaucum*, with  $g_s$  values  
393 remaining similar in each ozone treatment (Table S7). Positive, tightly coupled  
394 relationships between  $A_{\text{sat}}$  and  $g_s$  were found for *E. coracana*, *P. glaucum* and *P.*  
395 *vulgaris* ( $R^2M = 0.86, 0.63$  and  $0.66$  respectively,  $p < 0.001$  for all, Fig 4b-d) and less  
396 so for *T. aestivum* ( $R^2M = 0.52$ ,  $p < 0.001$ ; Figure 4a). The relationships were all linear  
397 within the range tested, although it should be noted that for *T. aestivum* this  
398 relationship was largely driven by datapoints with very low  $A_{\text{sat}}$ , when chlorophyll  
399 content had also been severely reduced and there was a large effect of senescence

400 and/or ozone damage. For the crops tested (*E. corcana* and *P. glaucum*), ozone did not  
401 negatively affect the slope of the  $A_{\text{sat}}$  vs.  $g_s$  relationships, in fact, for *E. corcana*, at  
402 high levels of  $g_s$ ,  $A_{\text{sat}}$  was slightly higher in the high ozone treatment ( $g_s * \text{ozone}$ ,  $p <$   
403 0.01). All model results are summarised in the Supplementary Information, Table S8.

404

### 405 3.3 Yield and grain weight

#### 406 3.3.1 *T. aestivum*

407 For *T. aestivum*, there was a decrease in the total yield at high ozone ( $p < 0.001$ ), with  
408 the mean yield at high ozone ( $22 \text{ g} \pm 1.2 \text{ SE}$ ) significantly lower than both low ( $37 \text{ g}$   
409  $\pm 1.2 \text{ SE}$ ) and medium ( $40 \text{ g} \pm 0.8 \text{ SE}$ ) ozone. The average yield across cultivars in  
410 the low and medium ozone treatments was not significantly different. There was a  
411 statistically significant difference in the response of different wheat cultivars to ozone  
412 (ozone and cultivar interaction,  $p < 0.001$ ). For the African cultivars, ozone sensitivity  
413 was ranked ‘Korongo’ > ‘Wren’ > ‘Njoro’ > ‘Hawk’ > ‘Eagle’ (Figure 5a; Table S1).  
414 ‘Korongo’ was the most sensitive of the African cultivars overall, with the average  
415 yield at high ozone 53% lower than at low ozone. In comparison, the least sensitive  
416 African cultivar, ‘Eagle’, only showed a 10% decrease in average yield in the high  
417 compared to the low ozone treatment.

418

419 For all Kenyan cultivars, there was a decrease in 1000-grain weight with increasing  
420 ozone ( $p < 0.001$ , Figure 6a). The average 1000-grain weight at high ozone was  
421 between 18 and 36% lower than at the low ozone treatment for the different cultivars.  
422 Although there was some variation in sensitivity, differences between cultivars were  
423 less marked than for total yield (Table S2) and there was no overall difference in the  
424 response of different *T. aestivum* cultivars to ozone (ozone and cultivar interaction,  $p$

425 > 0.05) for 1000-grain weight. The number of *T. aestivum* ears per pot was higher in  
426 the high ozone treatment ( $\bar{x} = 27 \pm 5$  sd) than the low ozone treatment ( $\bar{x} = 24 \pm 4$  sd)  
427 ( $p < 0.05$ ). However, the number of grains per ear were found to decrease with  
428 increasing ozone ( $p < 0.001$ ). This varied with cultivar (ozone \* cultivar interaction,  $p$   
429  $< 0.001$ ). The African cultivar ‘Korongo’ and the UK cultivar ‘Skyfall’ showed a  
430 significant reduction in the calculated number of grains per ear with increasing ozone  
431 treatment, whereas the other African cultivars showed no significant differences (data  
432 not presented).

433

### 434 3.3.2 *E. coracana*

435 Overall, there was no clear effect of ozone on total seed head weight for *E. coracana*  
436 (Figure 5b). There was some evidence of a delay in seed development with increasing  
437 ozone treatment, of up to 10 days, but this was not quantifiable statistically. Seed heads  
438 were harvested when they were ready so that harvest occurred at the same  
439 developmental stage. Results showed that the average total seed weight in the high  
440 ozone treatment was 32% higher than in the low ozone treatment, ( $p = 0.051$ ), and  
441 there was no overall difference in the response of each cultivar to the ozone treatments  
442 (interaction,  $p > 0.05$ ). For the average weight per seed head, there was no significant  
443 difference in the effect of ozone between cultivars, and the overall effect of ozone was  
444 to increase the weight per seed head (average seed head weight was  $4.04 \text{ g} \pm 0.4 \text{ SE}$   
445 for the low ozone treatment,  $4.95 \text{ g} \pm 0.37 \text{ SE}$  for medium ozone and  $4.80 \text{ g} \pm 0.34 \text{ SE}$   
446 for high ozone,  $p < 0.05$ ) Figure 6b).

447

448 3.3.3 *P. glaucum*

449 *P. glaucum* showed no overall significant ozone effect on total yield, and no difference  
450 in response between cultivars (Figure 5c). Similarly there was no overall effect of  
451 ozone on the weight per seed head (Figure 6c) or significant difference on the effect  
452 of ozone between cultivars. *P. glaucum* showed a high variation between replicates  
453 per treatment.

454

455 3.3.4 *P. vulgaris*

456 For *P. vulgaris*, there was a decrease in total yield with increasing ozone ( $p < 0.01$ ),  
457 with variation in the response of the different cultivars to ozone (ozone and cultivar  
458 interaction,  $p < 0.05$ ; Figure 5d, Table S3). The cultivar ‘Pinto’ was the most sensitive  
459 to ozone, with the average yield at high ozone 75% lower than that in low ozone ( $p <$   
460  $0.05$ ). Turtle and Orca beans showed a 50% decrease in average yield at high  
461 compared to low ozone, although this was not statistically significant due to the high  
462 variation in yield within ozone treatments. The total yield of Cannellini also did not  
463 vary with ozone treatment ( $p > 0.05$ ). The weight per bean seed of *P. vulgaris* was  
464 significantly reduced ( $p < 0.01$ ) at high compared to low ozone, with the magnitude  
465 of effect dependent on cultivar (ozone and cultivar interaction,  $p < 0.05$ ) (Figure 6d;  
466 Table S4). For Pinto, the weight per bean seed was 53% lower in the high ozone  
467 compared to the low ozone treatment ( $p < 0.001$ ). Turtle and Cannellini beans showed  
468 an average decrease in individual bean weight in high compared to low ozone of 33%  
469 and 16% respectively, although this was not statistically significant, and there was no  
470 effect of ozone on the individual bean weight of the cultivar ‘Orca’. Model results for  
471 all crop species are summarised in the Supplementary Information, Table S9.

472

### 473 3.4 $G_{\max}$

474  $G_{\max}$  was variable both between crop species and between cultivars of the same  
475 species (Table 3).  $G_{\max}$  was approximately four times higher for *T. aestivum*, which  
476 had the highest  $g_{\max}$  of the crops tested, than for *E. coracana*, which had the lowest.  
477 *P. glaucum* and *P. vulgaris*  $g_{\max}$  were similar to each other, and approximately 25%  
478 less than that of *T. aestivum*. For the *T. aestivum*, *E. coracana* and *P. vulgaris* cultivars  
479 tested,  $g_{\max}$  varied by approximately  $\pm 20\%$  compared to the mean for the species. For  
480 the crops showing a clear effect of ozone on yield/1000-grain weight (*T. aestivum* and  
481 *P. vulgaris*), the cultivars with the higher  $g_{\max}$  were not those ranked as the most  
482 sensitive to ozone in terms of yield. This was also the case for the visible ozone injury  
483 ranking (data not presented).

## 484 4 Discussion

485 This study has shown that ozone pollution in sub-Saharan Africa has the potential to  
486 reduce crop yield, particularly for wheat and beans, which are among the staple food  
487 crops for the region. Large decreases in yield of Kenyan *T. aestivum* cultivars were  
488 found. *T. aestivum* is known to be one of the most sensitive crops to ozone pollution  
489 of those crops that have been tested (Mills et al., 2007; Mills and Harmens, 2011), and  
490 for total yield the ozone-sensitivity of the Kenyan cultivar ‘Korongo’ was similar to  
491 the ozone-sensitivity of the European cultivar ‘Skyfall’, which has previously been  
492 identified as a very sensitive European cultivar (Harmens et al., 2018). Dry beans,  
493 commonly grown as a source of protein in many parts of the world, particularly in  
494 subsistence agriculture in tropical countries, were also very sensitive to ozone  
495 pollution and showed large reductions in yield, especially for the cultivar ‘Pinto’.  
496 There is less documented evidence of sensitivity to ozone for beans compared to that  
497 for wheat, however, the results from this study match those of previous studies, largely

498 on European and American peas and beans, which have also demonstrated that these  
499 are sensitive to ozone compared to other crops (Mills et al., 2007; Mills and Harmens,  
500 2011).

501

502 In addition to total yield, there were large reductions in 1000-grain/seed weight for *T.*  
503 *aestivum* and *P. vulgaris* (for the Pinto cultivar). 1000-grain/seed weight is related to  
504 commodity value, particularly when crops are graded for sale. There is not a  
505 straightforward link between grain size and nutritional quality, as growth dilution of  
506 some nutritional aspects can occur, e.g. the protein content of wheat tends to increase  
507 as grain size decreases, however, this may not compensate for the reduction in yield  
508 so that total protein yield of wheat is still reduced (Pleijel et al., 1999). The seed coat  
509 is relatively thick for *P. vulgaris*, and is a much larger proportion of the total weight  
510 for small beans compared to large beans. A previous study using adzuki beans showed  
511 that protein content was higher in large beans (26.1%) compared to small beans  
512 (22.3%) for the variety ‘WSU 262’ (Baik and Czuchajowska, 1999), therefore, it  
513 would be anticipated that there would be a considerable reduction in total protein  
514 content in small beans compared to large beans, in addition to the reduction in total  
515 yield for this crop.

516

517 For *T. aestivum*, the ranking of cultivars for ozone sensitivity in terms of visible leaf  
518 injury was the same as that for ozone sensitivity in terms of yield reduction. However,  
519 for *P. vulgaris* the ranking of sensitivity to ozone of the cultivars was different for  
520 these two measures. This could be explained by the different strategies of growth by  
521 different crops, as *P. vulgaris* can continue to grow leaves to replace those damaged  
522 by ozone, whereas for cereal crops such as *T. aestivum* no new leaves are grown

523 following the emergence of the flag leaf. Therefore, for *P. vulgaris*, a range of ozone  
524 tolerance mechanisms can be relevant in addition to those that maintain photosynthetic  
525 function of existing leaves.

526 For the crops *T. aestivum* and *P. vulgaris* it is likely that the reduction in yield is due  
527 to an ozone-induced reduction in chlorophyll, which therefore reduces photosynthetic  
528 capacity during the grainfill stage, as  $A_{\text{sat}}$  was closely coupled to chlorophyll content  
529 for these species. This is further supported by the reduction in grain size for these crops,  
530 indicating a lack of photosynthate at this time. Ozone-induced reductions in  
531 chlorophyll content were found in the current study, and reductions have previously  
532 been shown for a variety of crops including wheat and maize (Bagard et al., 2015) and  
533 soybean (Betzberger et al., 2010), with these studies relating the reduction in  
534 chlorophyll content to reduced photosynthesis.

535

536 It has previously been shown for several crops that the time of highest sensitivity to  
537 stress is during anthesis and grain filling, e.g. temperature for *T. aestivum* (Ferris et  
538 al., 1998) and sorghum (Prasad et al., 2015), drought for *P. glaucum* (Mahalakshmi et  
539 al., 1987) and ozone for *P. vulgaris* (Salvatori et al., 2013). Anthesis has been  
540 identified as the most ozone-sensitive growth stage in wheat due to  $g_{\text{max}}$  being highest  
541 at this time (Pleijel et al., 2007). There is also evidence from other studies that abiotic  
542 stress can cause the grainfill stage to be shortened (Prasad et al., 2008) or the rate of  
543 grainfill to be reduced (Dias and Lidon, 2009), highlighting the importance of  
544 maintaining photosynthetic activity during this time.

545

546 The effect of ozone on the staple tropical food crops *E. coracana* and *P. glaucum* has  
547 not previously been determined. The current study suggests that the total yield of *E.*

548 *coracana* was not significantly affected by ozone, however, there was a lot of variation  
549 in the collected data for each cultivar. This study has shown that individual seed head  
550 weight of *E. coracana* increased slightly when ozone was increased. The current study  
551 has also indicated no significant effects of ozone on the yield of *P. glaucum*, however,  
552 the exposure period for *P. glaucum* was during the vegetative stages only (because it  
553 grew too large for the ozone exposure facility) and therefore an impact on yield may  
554 have become apparent if *P. glaucum* was exposed to ozone during the anthesis and/or  
555 grain-filling stages. The data for *E. coracana* and *P. glaucum* was based on seedhead  
556 weight rather than grain weight, however, we believe that this is representative of yield  
557 as when seeds were successfully extracted these comprised >90% of the total seedhead  
558 weight.

559

560 Both *E. coracana* and *P. glaucum* are C<sub>4</sub> plants and the nature of the C<sub>4</sub> pathway  
561 means that photosynthetic machinery is further isolated from the external air, as a  
562 consequence of adaptation to reduce CO<sub>2</sub> leakage. These adaptations in C<sub>4</sub> plants  
563 include a high concentration of chloroplasts in tightly fitted bundle-sheath cells, with  
564 the loosely arranged mesophyll cells (also containing chloroplasts) between these and  
565 the air spaces within the leaf (Esau, 1977). Although there was no evidence of reduced  
566 chlorophyll content and a subsequent limitation to photosynthesis, visible leaf-injury  
567 was extensive (particularly for *E. coracana*) very early in the ozone exposure period,  
568 indicating a detrimental impact causing leaf damage early in the exposure period.  
569 However, the extent of visible leaf-injury to ozone during this time may not be  
570 indicative of the sensitivity to ozone during anthesis and grainfill for this species. It is  
571 possible that up-regulation of antioxidant defence pathways occurred within these  
572 species so that they were more resilient to subsequent stress (Di Baccio et al, 2008;

573 Chen and Gallie, 2005). Xanthophyll pigments are used to effectively dissipate excess  
574 energy from photosynthesis pigments to reduce energy loss from photorespiration in  
575 C<sub>4</sub> plants as well as in C<sub>3</sub> plants (Shay and Kubien, 2012), therefore, increased  
576 xanthophyll production in leaves in response to ozone stress may simultaneously  
577 increase photosynthetic efficiency.

578

579 Interestingly, for some crops A<sub>sat</sub> was tightly coupled to g<sub>s</sub>, whereas for others, A<sub>sat</sub>  
580 was tightly coupled to chlorophyll content. This may be related to the photosynthetic  
581 pathway of the species used as A<sub>sat</sub> and g<sub>s</sub> were tightly coupled for the C<sub>4</sub> plants *E.*  
582 *coracana* and *P. glaucum*. The C<sub>4</sub> photosynthetic pathway uses water more efficiently  
583 than the C<sub>3</sub> type, as carbon dioxide can be concentrated around Rubisco in the bundle  
584 sheath cells of C<sub>4</sub> plants. This may be particularly important when carbon dioxide  
585 supply is limited due to water stress, as water-use efficiency is increased and  
586 photosynthesis can occur with very low stomatal conductions, and is therefore more  
587 commonly found in plants of arid conditions. In our study we kept the plants well-  
588 watered, however, it has previously been shown that photosynthesis in water stressed  
589 *Setaria spachelata* (C<sub>4</sub>) was mainly limited by stomatal rather than non-stomatal  
590 (biochemical) limitations (Da Silva and Arrabaça, 2004), implying that in arid field  
591 conditions C<sub>4</sub> plants would still have reduced stomatal conductance and, therefore,  
592 ozone uptake. In contrast, for *T. aestivum* and *P. vulgaris* there was a close coupling  
593 to chlorophyll index, showing non-stomatal limitations to photosynthesis for these C<sub>3</sub>  
594 species and indicating that light-saturated photosynthesis is more determined by the  
595 capacity for light harvesting and CO<sub>2</sub> fixation rather than by stomatal control of CO<sub>2</sub>  
596 uptake.

597

598 The tight relationships between chlorophyll content and  $A_{\text{sat}}$  for *T. aestivum* and *P.*  
599 *vulgaris* also suggests that crop management strategies to maintain leaf chlorophyll  
600 content and delay leaf senescence during ozone exposure may help to reduce yield  
601 losses. However, whereas standard farming practices may be to apply additional  
602 nitrogen-based fertiliser to increase leaf greenness, this may not be effective if the  
603 cause of the leaf senescence is ozone exposure (Harmens et al., 2017; Broberg et al.,  
604 2017). Strategies to increase detoxification capacity within the leaves, or to reduce  
605 stomatal flux by either reducing stomatal opening or reducing ambient ozone  
606 concentrations could be more effective in this case. It has previously been shown that  
607 biochemical and molecular responses were good indicators of ozone-sensitivity of  
608 wheat cultivars in open-top chamber experiments (Fatima et al., 2018; Feng et al.,  
609 2016), including antioxidants such as ascorbate, total thiol and glutathione.

610

611 The large variation in sensitivity to ozone of the different cultivars tested indicates that  
612 there is potential for selection of ozone tolerant cultivars in regions where ozone  
613 concentrations are already high, or are set to increase further in the future, to maintain  
614 crop production in the longer term. There are already strategies to improve resistance  
615 to drought and heat stress for several tropical crops including *P. glaucum* (Serraj et  
616 al., 2005). In the near future this could include selection of existing cultivars that may  
617 be more resistant to the local pollution climate, but in the longer term selective  
618 breeding could be used to increase the prevalence of traits or genes associated with  
619 ozone resistance. An ideotype for an ozone-tolerant crop has been suggested, which  
620 includes target traits of increased water-use efficiency, low stomatal conductance, high  
621 antioxidant capacity and balanced redox homeostasis and programmed cell-death  
622 pathways, as ozone-sensitivity can be a consequence of some traits identified when

623 developing high-yielding varieties (Mills et al., 2018c). Studies have identified some  
624 genetic loci associated with ozone resistance and/or susceptibility in wheat and rice  
625 (e.g. Ainsworth et al., 2008; Frei, 2015, Frei et al., 2010). These could be related to  
626 biochemical processes and the efficiency of detoxification (Biswas and Jiang, 2011)  
627 or ozone induced stomatal closure to reduce ozone uptake (Kangasjärvi et al., 2005).  
628

## 629 5 Conclusions

630 Tropospheric ozone pollution can cause visible leaf-damage to tropical crop plants,  
631 which can result in reduced chlorophyll content in some cases. Crop yield and 1000-  
632 grain weight were reduced by ozone for *T. aestivum* and *P. vulgaris*, whereas the  
633 response for the C4 species *P. glaucum* and *E. coracana* was less clear. The Kenyan  
634 cultivars of *T. aestivum* tested in this study were in a similar range of ozone sensitivity  
635 as European cultivars, which are known to be ozone-sensitive. Therefore, there is a  
636 risk that tropospheric ozone can reduce food production in tropical regions, including  
637 Africa, where there is a high dependence on subsistence agriculture. Thus, there is an  
638 urgent need to measure the ozone concentrations in subsistence agriculture regions  
639 and to test a wider variety of tropical and temperate crops from these areas using the  
640 representative growing conditions in order to quantify the reduction in food production  
641 that may occur due to ozone pollution in these regions in current and future climate  
642 and environmental conditions.

1012

1013 **Table 1:** Summary of experimental timings for the crops used.

Crop	<i>T. aestivum</i>	<i>E. coracana</i>	<i>P. glaucum</i>	<i>P. vulgaris</i>
Unheated/heated (ambient temperature + 7°C)	unheated	heated	heated	heated
Number of cultivars	5 Kenyan + 1 UK	6	4	4
Number of plants per pot	9	4	2	1
Start of ozone treatment	18 <sup>th</sup> May	1 <sup>st</sup> June	24 <sup>th</sup> May	1 <sup>st</sup> June
End of ozone treatment <sup>1</sup>	25 <sup>th</sup> July	26 <sup>th</sup> October	29 <sup>th</sup> June (moved to glasshouse as plants became too big for solardomes)	Pinto: 26 <sup>th</sup> July Turtle: 2 <sup>nd</sup> August Orca: 21 <sup>st</sup> August Cannellini: 25 <sup>th</sup> August
Nutrient addition	25 <sup>th</sup> May, 80 kg N/ha; 16 <sup>th</sup> June, 80 kg N/ha	16 <sup>th</sup> June, 80 kg N/ha; 8 <sup>th</sup> August, 80 kg N/ha	25 <sup>th</sup> May, 80 kg N/ha; 22 <sup>nd</sup> June, 80 kg N/ha;	22 <sup>nd</sup> June, 40 kg N/ha; 14 <sup>th</sup> July, 40 kg N/ha;
Dates of A <sub>sat</sub> measurements	28 <sup>th</sup> June, 5 <sup>th</sup> July, 11 <sup>th</sup> July,	12 <sup>th</sup> July, 26 <sup>th</sup> -27 <sup>th</sup> July, 2 <sup>nd</sup> August	4 <sup>th</sup> August, 14 <sup>th</sup> -15 <sup>th</sup> August	6 <sup>th</sup> July, 4 <sup>th</sup> August, 8 <sup>th</sup> August
Harvest of yield	25 <sup>th</sup> July-1 <sup>st</sup> August	28 <sup>th</sup> September – 26 <sup>th</sup> October	5 <sup>th</sup> September	Pinto: 26 <sup>th</sup> July Turtle: 2 <sup>nd</sup> August Orca: 21 <sup>st</sup> August Cannellini: 25 <sup>th</sup> August

1014 <sup>1</sup> The exposure length varied for the different bean varieties due to the differences in  
 1015 growing season length of the varieties used.

1016

1017

1018 **Table 2:** Ozone concentrations and climatic conditions for the treatments over the

1019 experimental period.

Ozone treatment	Temperature regime	Ozone, weekly mean (ppb)	Ozone, mean daily max. (ppb)	Temperature, daylight mean (°C)	VPD, daylight mean (kPa)	PAR, 12h mean (mmol/m <sup>2</sup> /s)
Low	Ambient	25.6±0.3	32.5±1.0	20.3±0.3	0.61±0.1	487±21
Medium	Ambient	40.2±1.3	67.3±2.8	20.3±0.3	0.61±0.1	487±21
High	Ambient	45.8±2.1	84.0±4.5	20.3±0.3	0.61±0.1	487±21

Low	Ambient + 7°C	25.4±0.5	33.9±0.7	27.2±0.3	1.89±0.1	487±21
Medium	Ambient + 7°C	40.6±1.3	70.6±2.7	27.7±0.3	2.05±0.1	487±21
High	Ambient + 7°C	47.8±2.0	93.0±4.3	27.3±0.3	1.87±0.1	487±21

1020

1021

1022 **Table 3:** Calculated  $g_{\max}$  for the crop type and cultivars tested.

	<i>T. aestivum</i>	<i>E. coracana</i>	<i>P. glaucum</i>	<i>P. vulgaris</i>
$G_{\max}$ (mmol O <sub>3</sub> m <sup>-2</sup> PLA s <sup>-1</sup> )	Mean: 440	Mean: 110	Mean: 350	Mean: 340
	Eagle 10: 345	GuluE: 140	ICMV221: 370	Pinto: 365
	Hawk 12: 530	KNE624: 100	KATPM1: 310	Turtle: 400
	Korongu: 375	KNE814: 125	Okashana: 325	Orca: 295
	Njoro BWII: 530	Okhale: 110	Shibe: 355	Cannellini: 300
	Wren: 425	P224: 90		
		U15: 110

1025 **Figure Legends:**

1026

1027 **Figure 1:** A) Weekly target diurnal ozone concentrations for the treatments used. Note  
1028 that the target concentrations in heated and unheated solardomes were the same, and  
1029 B) Achieved ozone concentrations for a 'typical' day (8<sup>th</sup> June, 2017).

1030

1031 **Figure 2:** Predicted probabilities of leaf injury being present: mild (<5% of leaf  
1032 affected), moderate (5-25%) or severe (>25%) after 2 weeks of exposure to low,  
1033 medium and high ozone for *T. aestivum* (wheat), *E. coracana* (finger millet), *P.*  
1034 *glaucum* (pearl millet) and *P. vulgaris* (common bean). Wheat cultivar Kor. =  
1035 Korongo. Bean cultivar Can. = Cannellini.

1036

1037 **Figure 3.** Relationship between CCI (Chlorophyll Content Index) and  $A_{\text{sat}}$  ( $\mu\text{mol m}^2$   
1038  $\text{s}^{-1}$ ) at low, medium and high ozone levels for a) *T. aestivum*, b) *E. coracana*, c) *P.*  
1039 *glaucum* and d) *P. vulgaris*. Plotted lines use model fitted values.

1040

1041 **Figure 4.** The effect of increasing stomatal conductance ( $g_s$ ,  $\text{mol H}_2\text{O m}^{-2} \text{ PLA s}^{-1}$ ) on  
1042  $A_{\text{sat}}$  ( $\mu\text{mol m}^{-2} \text{ s}^{-1}$ ) for a) *T. aestivum*, b) *E. coracana*, c) *P. glaucum* and d) *P. vulgaris*.  
1043 Measurements at different ozone treatments are represented by different symbols for  
1044 *E. coracana* and *P. glaucum*. Plotted lines use model fitted values.

1045

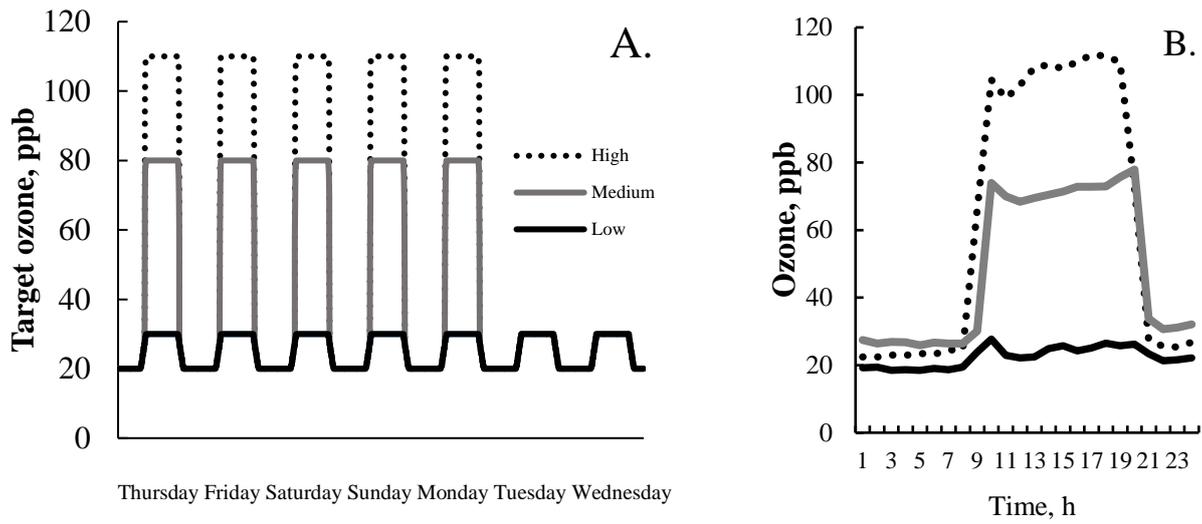

1046 **Figure 5.** The effect of increasing ozone levels (low, medium and high treatments) on  
1047 total yield for different cultivars of a) *T. aestivum*, b) *E. coracana*, c) *P. glaucum* and  
1048 d) *P. vulgaris*. Error bars are  $\pm$  se.

1049

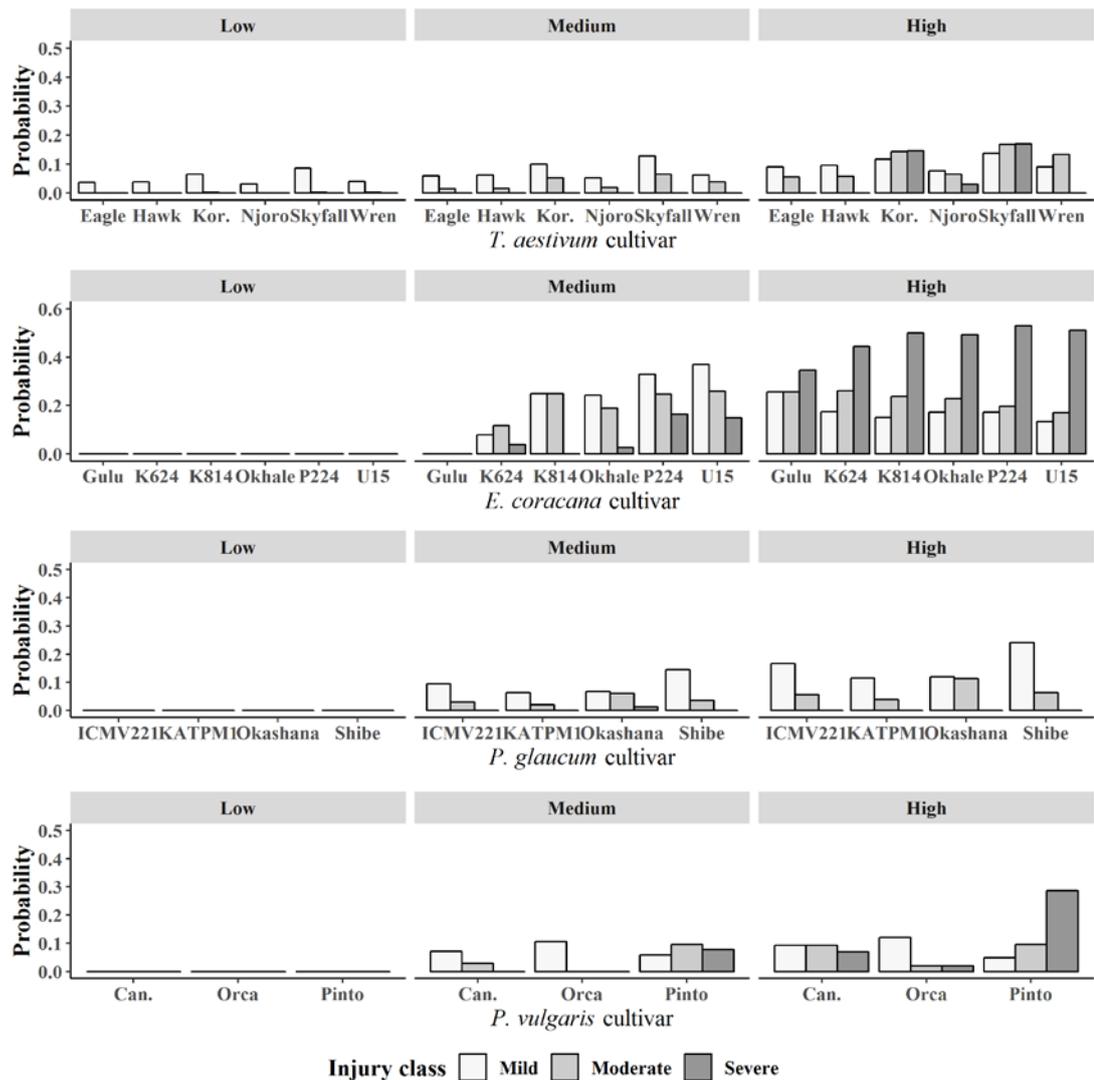

1050 **Figure 6.** The effect of increasing ozone levels on grain/seed weight for different  
1051 cultivars of *T. aestivum* and *P. vulgaris* (a & d) and seed head weight (b & c) for *E.*  
1052 *coracana* and *P. glaucum*. Error bars are  $\pm$  se.

1053

1054

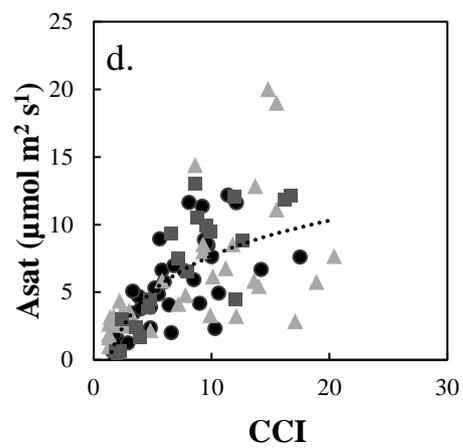

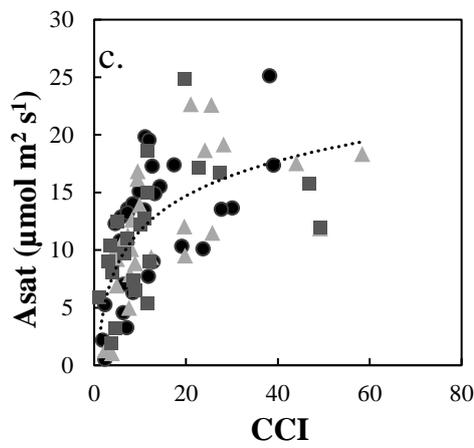

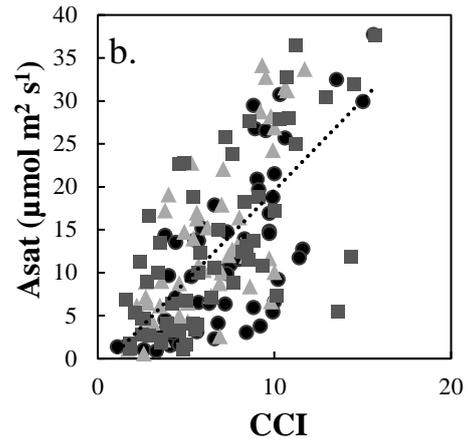

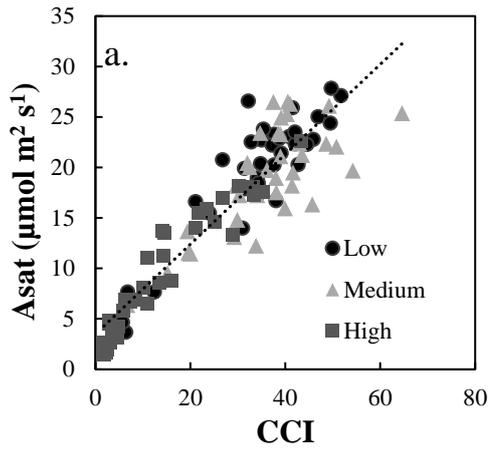

3 **Figure 1:** A) Weekly target diurnal ozone concentrations for the treatments used. Note that the target  
 4 concentrations in heated and unheated solardomes were the same, and B) Achieved ozone concentrations for  
 5 a 'typical' day (8<sup>th</sup> June, 2017).
