# Hydrological Summary for the United Kingdom 

#### Abstract

General October was an exceptionally warm and, after the first week, notably unsettled month. Successive pulses of frontal rainfall and, latterly, saturated catchment conditions saw the focus of hydrological concern swing decisively towards the risk of flooding across much of the UK. Exceptional peak flows were reported for a number of western and northern rivers with notable runoff rates extending well into November. These served to accentuate regional contrasts in water resources status. Very brisk increases in major reservoir stocks (e.g. > 30\% at Elan Valley in three weeks) helped ensure that overall stocks for England and Wales were appreciably above average by early November. However, October levels in some south-eastern reservoirs remained exceptionally low (the lowest for October at Weir Wood since its construction in 1953) and groundwater levels were very depressed in some southern Chalk outcrops. Correspondingly, flows in many spring-fed rivers continued to decline. October flows approached the lowest on record in a number of Chalk catchments and accumulated runoff totals (over 12 months) remain exceptionally low over much of southern Britain. The recent notably wet episode has left most impermeable catchments across the UK very vulnerable to further rainfall. In the drought affected areas, it has provided a platform (only) for a seasonal recovery in runoff and recharge rates; above average rainfall will still be needed throughout the coming winter to provide a healthy water resources outlook for 2006.

## Rainfall

In much of the UK, the dry early autumn weather continued into October; some central southern areas of England reported less than 5 mm of rain over the first 11 days. Thereafter, a sequence of vigorous frontal systems, many on a south-westerly airflow, produced notable rainfall totals over the following four weeks. The $9-12^{\text {th }}$ was an especially wet interlude; 24-hr rainfall totals included 98.6 mm at Braidlie in the Borders ( 91 mm at Carlisle) and 114 mm at Milford Haven on the $11^{\text {th }}$; the $24^{\text {th }}$ was also very wet over wide areas. Most low pressure systems tracked to the south of northern Scotland where some areas (e.g. much of Sutherland) reported $<50 \%$ of the October average rainfall. By contrast, the Borders were exceptionally wet - up to $250 \%$ - and totals across most of England and Wales exceeded $120 \%$; Northern Ireland was wet also. For E\&W it was the wettest month, by a substantial margin, since October 2004 but, significantly, the most modest positive anomalies tended to characterise those areas where the drought is most entrenched; a few areas of Kent failed to reach the October average. In most regions, rainfall over the last 6 months has been in the normal range but very substantial deficits remain in the 12-month timeframe. For E\&W, it was the 4th driest NovOct since 1975/76 but for parts of the South East (and central southern England), where deficiencies are $25 \%$ or more, a similar ranking applies over the last 70 years.

## Flows

October runoff totals for many index catchments were within the normal range but the considerable spatial and temporal variations which typify autumn river flows were heavily accentuated this October. Modest autumn flows were common during the first week but in most responsive catchments rapid recoveries began around the $10^{\text {th }}$, heralding significant flooding in many areas. On the 11th, the Teviot, at Hawick, exceeded its previous maximum flow (established in January this year) in a 42-yr record; around 200 properties were flooded. In Wales, Haverfordwest was flooded as the Western Cleddau recorded its highest level in 40-yr record. More localised flooding was also common as rainfall intensities exceeded urban drainage capacities (e.g. in Carlisle) or soil
infiltration capacities (e.g. surface runoff inundated vulnerable settlements near St Austell in Cornwall). Traffic disruption was severe and Flood Warnings were widespread, continuing into November. Some notable spates occurred in impermeable lowland catchments (e.g. on the Wey) but the depressed flows in many spring-fed rivers were of greater significance. Following 29 successive months with below average monthly flows, the Lambourn closely approached its early October minima (in a record from 1962). In such rivers, accumulated runoff totals testify to the drought's severity. The Aug-Oct runoff total for the Test vies with 1997 as the lowest in a series from 1957 and runoff over the last 12 months is among the lowest three on record for many catchments in eastern, central and southern England (parts of Northern Ireland also).

## Groundwater

October rainfall totals were appreciably above average across most aquifer outcrop areas but in the east and south substantial soil moisture deficits initially limited its effectiveness. The rainfall distribution favoured the more westerly and northerly aquifers but, as elsewhere, depressed groundwater levels, and the associated depth of the unsaturated zone, mitigated against a rapid response to the heavy rainfall from mid-month. Some signs of a seasonal recovery are evident (e.g. in the Carboniferous Limestone) but, generally, mid-October levels underlined the exceptional depletion in groundwater resources over the last two years. In the Permo-Triassic sandstones at Morris Dancers and Bussels groundwater levels closely approached their lowest October levels on record; for the latter it was the lowest level for any month since 1992. In the Chalk, levels at Chilgrove were around 40 m below their early 2003 peak and the mean October level eclipsed 1976 as the lowest in a series from 1836 (but levels began to recover by month end). Levels are less depressed, but still well below average, throughout much of the Chalk outcrops of southern England. The Oct/early Nov rainfall has initiated the 2005/06 recharge season in most areas but further sustained rainfall will be needed to restore groundwater levels to within the normal winter range.

Above average

May 2005 - October 2005

November 2004 - October 2005

## Rainfall accumulation maps

Rainfall over the May-October period was within 5\% of the average for England and Wales, Scotland and Northern Ireland - with significant regional anomalies confined to the north-west and south-east of Britain. This contrast is heavily emphasised in the 12-month timeframe where the focus of the drought - across southern Britain - is clearly evident.

## River flow . . . River flow

## River flows

*Comparisons based on percentage flows alone can be misleading. A given percentage flow can represent extreme drought conditions in permeable catchments where flow patterns are relatively stable but be well within the normal range in impermeable catchments where the natural variation in flows is much greater. Note: the period of record on which these percentages are based varies from station to station. Percentages may be omitted where flows are under review.

## River flow . . . River flow

## River flow hydrographs

The river flow hydrographs show the daily mean flows together with the maximum and minimum daily flows prior to November 2004 (shown by the shaded areas). Daily flows falling outside the maximum/minimum range are indicated where the bold trace enters the shaded areas.

## Groundwater . . . Groundwater

Groundwater levels normally rise and fall with the seasons, reaching a peak in the spring following replenishment through the winter (when evaporation losses are low and soil moist). They decline through the summer and early autumn. This seasonal variation is much reduced when the aquifer is confined below overlying impermeable strata. The monthly max., min. and mean levels are displayed in a similar style to the river flow hydrographs. Note that most groundwater levels are not measured continuously - the latest recorded levels are listed overleaf.

## Groundwater . . Groundwater

## Groundwater levels - October 2005

The rankings are based on a comparison between the average level in the featured month (but often only single readings are available) and the average level in each corresponding month on record. They need to be interpreted with caution especially when groundwater levels are changing rapidly or when comparing wells with very different periods of record. Rankings may be omitted where they are considered misleading.
Notes: i. The outcrop areas are coloured according to British Geological Survey conventions.
ii. Yew Tree Farm levels are now received quarterly.

# National Hydrological Monitoring Programme 

The National Hydrological Monitoring Programme (NHMP) was instigated in 1988 and is undertaken jointly by the Centre for Ecology and Hydrology Wallingford (formerly the Institute of Hydrology - IH) and the British Geological Survey (BGS). Financial support for the production of the monthly Hydrological Summaries is provided by the Department for Environment, Food and Rural Affairs (Defra), the Environment Agency (EA), the Scottish Environment Protection Agency (SEPA), the Rivers Agency (RA) in Northern Ireland, and the Office of Water Services (OFWAT).

## Data Sources

River flow and groundwater level data are provided by the Environment Agency, the Environment Agency Wales, the Scottish Environment Protection Agency and, for Northern Ireland, the Rivers Agency and the Department of the Environment (NI). In all cases the data are subject to revision following validation (flood and drought data in particular may be subject to significant revision).

Reservoir level information is provided by the Water Service Companies, the EA, Scottish Water and the Northern Ireland Water Service.

The National River Flow Archive (maintained by CEH Wallingford) and the National Groundwater Level Archive (maintained by BGS) provide the historical perspective within which to examine contemporary hydrological conditions.

## Rainfall

Most rainfall data are provided by the Met Office (see opposite). To allow better spatial differentiation the rainfall data for Britain are presented for the regional divisions of the precursor organisations of the EA and SEPA. Following the discontinuation of the Met Office's CARP system in July 1998, the areal rainfall figures have been derived using several procedures, including initial estimates based on MORECS*. Recent figures have been produced by the Met Office, National Climate Information Centre (NCIC), using a technique similar to CARP. A significant number of additional monthly raingauge totals are provided by the EA and SEPA to help derive the contemporary regional rainfalls. Revised monthly national and regional rainfall totals for the post-1960 period (together with revised 1961-90 averages) were made available by the Met Office in 2004; these have been adopted by the NHMP. As with all regional figures based on limited raingauge networks the monthly tables and accumulations (and the return periods associated with them) should be regarded as a guide only.
*MORECS is the generic name for the Met Office services involving the routine calculation of evaporation and soil moisture throughout Great Britain.

The Met Office
FitzRoy Road
Exeter

The National Hydrological Monitoring Programme depends on the active cooperation of many data suppliers. This cooperation is gratefully acknowledged.

## Subscription

Subscription to the Hydrological Summaries costs $£ 48$ per year. Orders should be addressed to:

Hydrological Summaries
National Water Archive
CEH Wallingford
Maclean Building
Crowmarsh Gifford
Wallingford
Oxfordshire
