# Hydrological Summary for the United Kingdom 

## General

January was a very unsettled month with few dry days and most regions registered appreciably above average rainfall; as importantly, three-month rainfall totals are also above average. Consequently reservoir stocks continued their brisk December improvement and, despite drawdowns in some impoundments to provide additional flood alleviation capacity, overall stocks for England and Wales are now around $4 \%$ above average for the late winter. Over wide areas, river flows approached, or exceeded bankfull, during January and moderate floodplain inundation was a common occurrence; at month-end many catchments were very vulnerable to further rainfall. Below average January runoff totals were largely confined to spring-fed rivers in the English Lowlands. In most major aquifers groundwater levels increased substantially over the month and the near-saturated soil conditions provide the opportunity for further significant late-winter recharge. 1990 and 1995 serve as recent reminders that a wet winter cannot completely eliminate the possibility of drought stress in the following summer. Nonetheless, it is a measure of the UK's resilience to within-year drought episodes that the elimination of less than half of the rainfall deficiencies (built-up by late October) has secured a healthy water resources outlook.

## Rainfall

January was a generally mild month punctuated by a freezing interlude as an Arctic airflow brought widespread snowfall across much of the UK late in the month substantial accumulations were reported on the 28th (e.g. around 30 cm at Fylingdales and Glenlivit). Gales and blizzards were common in northern Scotland but, to the south, mild and damp conditions predominated. Many areas reported only 3 or 4 dry days in the month and vigorous frontal systems produced significant precipitation totals on a number of occasions. The last few days of the month were especially wet (Eskdalemuir reported 62 mm on the 28th and parts of Northern Ireland received almost half their January total in the last couple of days) - initiating an exceptionally wet spell that continued into February. A few areas, mostly in eastern Scotland, reported slightly below average January rainfall totals but much of Britain exceeded $120 \%$ with a few areas (e.g. the North York Moors approaching 200\%). For the UK as a whole, January was the wettest month since Oct 2002 and all regions have had above average rainfall since last October (only marginally so in the South-West). Nov-Jan is, on average, the wettest period of the year (and evaporative losses are modest). Thus the positive rainfall anomalies in this timespan resulted in substantial improvements in water resources despite appreciable long term rainfall deficiencies (beginning Feb 2003) remaining, in parts of north-east Britain especially.

## River FIow

Most rivers experienced a wide range of flows in January but the overall runoff pattern was in marked contrast to the depressed flows characterising most catchments in October. In the interim, the focus of hydrological concern has switched decisively to the risk of flooding. Flood Alerts and Warnings were common in January and snowmelt at month end, together with heavy rainfall, triggered notable spates in many catchments. The River Ewe registered its second highest flow in the last 10 years and the Dee (north Wales) closely approached its highest January flow on record - heralding severe flooding in early

February, in the Conwy Valley particularly. The lateJanuary spates boosted runoff totals to well above average in the great majority of index catchments. Flows in some, mostly eastern, spring-fed rivers remained below average but the belated seasonal recovery has gathered momentum over the last 6-8 weeks. In many areas the January runoff terminated lengthy sequences of below average monthly flows - extending back to last February on the Thames, and longer in many Scottish catchments. A measure of the contrast with flow patterns in 2003 is provided by the Aberdeenshire Dee - above average January flows followed its lowest annual runoff total in a series from 1929.

## Groundwater

Soils remained at, or very close to, saturation throughout January and with modest evaporative demands, infiltration rates were well above average throughout most aquifer units - exceeding $150 \%$ of the Jan average in parts of the Chalk. The lag between infiltration and water-table response can be considerable (especially following a period of depressed groundwater levels) but January levels confirmed that a strong recovery is underway in almost all areas. In the southern Chalk (e.g. at Chilgrove and West Woodyates) levels have risen by 30 metres or more since the 2003 minima. Levels remain below average in the slower responding eastern outcrops where the recovery has only recently been initiated; nonetheless late-January levels were generally within the normal range. Steep recent recoveries characterise most limestone aquifers - in the Jurassic Limestone of the Cotswolds levels at Ampney Crucis, levels exceed the average having been at their lowest since 1996 in November. In contrast to the limestone and Chalk aquifers the recovery in most of the PermoTriassic sandstones outcrops (Bussels is an exception) is being generated from relatively healthy levels - a reflection of recharge patterns over several years. The recovery is now gathering momentum and most index boreholes are appreciably above average. Heavy late-January infiltration implies that further groundwater level rises may be anticipated in February.

## Rainfall . . . Rainfall . .

## Key

Sery wet Substantially above Sormal range

November 2003 - January 2004
February 2003 - January 2004

## Rainfall accumulation maps

The last three months added to a cluster of notably wet Nov-Jan periods; for the UK as a whole 9 out of the last 12 have registered well above average rainfall. Notwithstanding the recent sequence of wet months, provisional rainfall figures indicate that the Feb 2003 - Jan 2004 rainfall was the second lowest (in that timeframe) since 1976; parts of eastern Scotland being especially dry.

## River flows - January 2004

*Comparisons based on percentage flows alone can be misleading. A given percentage flow can represent extreme drought conditions in permeable catchments where flow patterns are relatively stable but be well within the normal range in impermeable catchments where the natural variation in flows is much greater. Note: the period of record on which these percentages are based varies from station to station. Percentages may be omitted where flows are under review.

## River flow . . . River flow

## Monthly river flow hydrographs

The river flow hydrographs show the monthly mean flow (bold trace), the long term average monthly flow (dotted trace) and the maximum and minimum flow prior to 2001 (shown by the shaded areas). Monthly flows falling outside the maximum/ minimum range are indicated where the bold trace enters the shaded areas.

## River flow . . . River flow

Notable runoff accumulations (a) December 2003 - January 2004, (b) February 2003 - January 2004

| Carron | 68 | $1 / 25$ |
| Naver | 75 | $2 / 26$ |
| Annacloy | 66 | $1 / 24$ |

## Groundwater . . . Groundwater

Groundwater levels normally rise and fall with the seasons, reaching a peak in the spring following replenishment through the winter (when evaporation losses are low and soil moist). They decline through the summer and early autumn. This seasonal variation is much reduced when the aquifer is confined below overlying impermeable strata. The monthly max., min. and mean levels are displayed in a similar style to the river flow hydrographs. Note that most groundwater levels are not measured continuously - the latest recorded levels are listed overleaf.

## Groundwater. . . Groundwater

## Groundwater levels - January 2004

The rankings are based on a comparison between the average level in the featured month (but often only single readings are available) and the average level in each corresponding month on record. They need to be interpreted with caution especially when groundwater levels are changing rapidly or when comparing wells with very different periods of record. Rankings may be omitted where they are considered misleading.
Notes: i. The outcrop areas are coloured according to British Geological Survey conventions.
ii. The Newbridge borehole supercedes Redbank (which was affected by groundwater abstraction). Yew Tree Farm levels are now received quarterly.

## Reservoirs . . . Reservoirs

## Guide to the variation in overall reservoir stocks for England and Wales

Comparison between overall reservoir stocks for England and Wales in recent years

These plots are based on the England and Wales figures listed below.

# National Hydrological Monitoring Programme 

The National Hydrological Monitoring Programme was instigated in 1988 and is undertaken jointly by the Centre for Ecology and Hydrology Wallingford (formerly the Institute of Hydrology - IH) and the British Geological Survey (BGS). Financial support for the production of the monthly Hydrological Summaries is provided by the Department for Environment, Food and Rural Affairs (Defra), the Environment Agency (EA), the Scottish Environment Protection Agency (SEPA), the Rivers Agency (RA) in Northern Ireland, and the Office of Water Services (OFWAT).

## Data Sources

River flow and groundwater level data are provided by the Environment Agency, the Environment Agency Wales, the Scottish Environment Protection Agency and, for Northern Ireland, the Rivers Agency and the Department of the Environment (NI). In all cases the data are subject to revision following validation (flood and drought data in particular may be subject to significant revision).

Reservoir level information is provided by the Water Service Companies, the EA, Scottish Water and the Northern Ireland Water Service.

The National River Flow Archive (maintained by CEH Wallingford) and the National Groundwater Level Archive (maintained by BGS) provide the historical perspective within which to examine contemporary hydrological conditions.

## Rainfall

Most rainfall data are provided by The Met Office (see opposite). To allow better spatial differentiation the rainfall data for Britain are presented for the regional divisions of the precursor organisations of the EA and SEPA. Following the discontinuation of The Met Office's CARP system in July 1998, the areal rainfall figures have been derived using several procedures, including initial estimates based on MORECS*. Recent figures have been produced by The Met Office, National Climate Information Centre (NCIC), using a technique similar to CARP. An initiative is underway with The Met Office to provide more accurate areal figures and, since October 1999, to include more raingauges in the analysis. A significant number of additional monthly rainfall totals are currently being provided by the Environment Agencies. As with all regional figures based on limited raingauge networks the monthly tables and accumulations (and the return periods associated with them) should be regarded as a guide only.
*MORECS is the generic name for the Meteorological Office services involving the routine calculation of evaporation and soil moisture throughout Great Britain.
