# Hydrological Summary for the United Kingdom 

## General

March was another relatively dry month and although winter rainfall (Oct-Mar) totals were close the average in most regions, longer term rainfall deficiencies remain very substantial across most of the UK. March rainfall totals were $<70 \%$ of average over wide areas but, with very modest evaporative demands, stocks in many reservoirs increased appreciably and, as is usual by early April, most were close to capacity (see page 10 for exceptions). Overall stocks for England and Wales were around $93 \%$ of capacity, marginally above the early April average, and considerably healthier than corresponding stocks in the drought conditions of 1993 and 1996. Relative to the recent past, groundwater levels are generally low for the early spring but mostly still within the normal range; however, recessions have again begun early, in eastern aquifer units especially. As is often the case, late spring rainfall will greatly influence the water resources outlook for the summer and autumn, particularly in the English Lowlands where soil moisture deficits are beginning to build. Substantially below average rainfall over the next 4-6 weeks could, very probably, be the precursor of depressed river flows and groundwater levels by the early autumn.

## Rainfall

March was, at turns, balmy and boisterous with precipitation mostly concentrated in the first three weeks. Gales produced significant rainfall and some wind damage on the 8th (e.g. on the Isle of Wight) and substantial rainfall totals were registered in northern Britain on the 19th (e.g. 60 mm at Loch Glascarnoch, Highland Region). However, many rain-bearing depressions passed to the north of the British Isles and most frontal incursions produced only modest rainfall totals. As a consequence, March rainfall was below average across the UK with the exception of a zone from the Cheviots to Northern Ireland (plus a few other localities). Large parts of eastern Britain registered less than $70 \%$ of the March average, the southern Pennines and Cheshire Plain being particularly dry. Provisional FebMar totals are higher than in 2003 but still well below average in most regions, notably so in the South East; for E\&W it was the 4th driest Feb-Mar since 1976. Rainfall over the winter half-year has been typified by large month-on-month variability but all regions registered Oct-Mar totals in the normal range (but for Northern Ireland it was the driest since 1986). Longer term deficiencies remain large; a few eastern catchments have reported below average rainfall in 10 of last 12 months and provisional data indicate that, for the UK as a whole, the 14-month period beginning in Feb 2003 was the driest since 1975/76.

## River Flows

Many rivers reported a wide range of flows in March, in northern regions of the UK especially. During the first week the continuation of the steep February recessions produced depressed flows in impermeable catchments across northern Britain; the Forth, Tweed, Ribble and Nith were amongst many index rivers eclipsing previous daily minimum flows for the March $10-17^{\text {th }}$ period. A sharp recovery in runoff rates then produced significant spates around the $19^{\text {th }}$ when localised flooding was reported in the Highlands. Steep recessions resumed thereafter and many rivers were again approaching seasonal minima by early April. March runoff totals were well below average
(typically, $<70 \%$ ) at almost all index gauging stations. The Tay reported its second lowest March flow in the last 20 years and, in England, the Trent registered its 3rd lowest March flow in a 47-year record, and many rivers reported their lowest March runoff since 1993 (e.g. the Sussex Ouse). Flows in rivers draining permeable catchments are less responsive to limited early spring rainfall, but seasonal recessions have begun in many Chalk streams, typically from well below average spring peaks - increasing the expectation of very low late summer flows. Importantly however, for most spring-fed rivers current flow rates substantially exceed corresponding values in recent drought years (e.g. 1997, 1992, 1991 and 1976).

## Groundwater

Although very moist soil moisture conditions were helpful for groundwater replenishment in March, rainfall across most outcrop areas was $<75 \%$ - and infiltration rates less than half - the long term average. As importantly, winter recharge totals were well below average across almost all aquifer outcrop areas. Groundwater levels in most index wells and boreholes normally peak in the late winter/early spring. In the absence of substantial late April recharge, the spring maxima in 2004 will, over wide areas, be their lowest for seven years with most recessions commencing from below average levels. Recessions are well established in much of the southern Chalk (e.g. at Chilgrove and Rockley) but levels continue to rise at the deep Therfield well. Levels are also falling in the Limestone aquifers but rising slowly in the slowest responding Permo-Triassic sandstones. Overall groundwater resources are substantially lower than at the corresponding time in 2003 (and, generally, for the 1998-2002 period). Nonetheless, most March groundwater levels were within the normal spring range; generally below average but well above the levels which characterised the early and mid-1990s, and much of the 1970s. Late-March soil moisture deficits were lower than in 2003 but a continuation of dry and warm conditions in late April may well terminate the recharge season in the east.

## Rainfall . . . Rainfall . .

## Key

Above average Sery wet

October 2003 - March 2004
February 2003 - March 2004

## Rainfall accumulation maps

Notwithstanding the substantially below average rainfall for February and March, the winter half-year rainfall totals were in the 83-105\% range for all regions of the UK. A contrasting picture emerges over the 14-month timeframe: Feb 2003March 2004 rainfall deficiencies are substantial throughout the country. In water resources terms, their significance is greatest in the English Lowlands but in a hydrological context, the deficiencies in eastern Scotland are most notable - the Tay region registering its driest such period since 1975/76.

## River flows - March 2004

*Comparisons based on percentage flows alone can be misleading. A given percentage flow can represent extreme drought conditions in permeable catchments where flow patterns are relatively stable but be well within the normal range in impermeable catchments where the natural variation in flows is much greater. Note: the period of record on which these percentages are based varies from station to station. Percentages may be omitted where flows are under review.

## River flow . . . River flow

## Monthly river flow hydrographs

The river flow hydrographs show the monthly mean flow (bold trace), the long term average monthly flow (dotted trace) and the maximum and minimum flow prior to 2001 (shown by the shaded areas). Monthly flows falling outside the maximum/ minimum range are indicated where the bold trace enters the shaded areas.

## River flow . . . River flow

## Groundwater . . . Groundwater

Groundwater levels normally rise and fall with the seasons, reaching a peak in the spring following replenishment through the winter (when evaporation losses are low and soil moist). They decline through the summer and early autumn. This seasonal variation is much reduced when the aquifer is confined below overlying impermeable strata. The monthly max., min. and mean levels are displayed in a similar style to the river flow hydrographs. Note that most groundwater levels are not measured continuously - the latest recorded levels are listed overleaf.

## Groundwater. . . Groundwater

## Groundwater levels - March 2004

The rankings are based on a comparison between the average level in the featured month (but often only single readings are available) and the average level in each corresponding month on record. They need to be interpreted with caution especially when groundwater levels are changing rapidly or when comparing wells with very different periods of record. Rankings may be omitted where they are considered misleading.
Notes: i. The outcrop areas are coloured according to British Geological Survey conventions.
ii. The Newbridge borehole supercedes Redbank (which was affected by groundwater abstraction). Yew Tree Farm levels are now received quarterly.

Details of the individual reservoirs in each of the groupings listed above are available on request. The featured reservoirs may not be representative of the storage conditions across each region; this can be particularly important during droughts. The storage figures relate to the 1988-2004 period only (except for West of Scotland and Northern Ireland where data commence in the mid-1990's). In some gravity-fed reservoirs (e.g. Clywedog) stocks are kept below capacity during the winter to provide scope for flood attenuation purposes.

## Location map . . . Location map

# National Hydrological Monitoring Programme 

The National Hydrological Monitoring Programme was instigated in 1988 and is undertaken jointly by the Centre for Ecology and Hydrology Wallingford (formerly the Institute of Hydrology - IH) and the British Geological Survey (BGS). Financial support for the production of the monthly Hydrological Summaries is provided by the Department for Environment, Food and Rural Affairs (Defra), the Environment Agency (EA), the Scottish Environment Protection Agency (SEPA), the Rivers Agency (RA) in Northern Ireland, and the Office of Water Services (OFWAT).

## Data Sources

River flow and groundwater level data are provided by the Environment Agency, the Environment Agency Wales, the Scottish Environment Protection Agency and, for Northern Ireland, the Rivers Agency and the Department of the Environment (NI). In all cases the data are subject to revision following validation (flood and drought data in particular may be subject to significant revision).

Reservoir level information is provided by the Water Service Companies, the EA, Scottish Water and the Northern Ireland Water Service.

The National River Flow Archive (maintained by CEH Wallingford) and the National Groundwater Level Archive (maintained by BGS) provide the historical perspective within which to examine contemporary hydrological conditions.

## Rainfall

Most rainfall data are provided by The Met Office (see opposite). To allow better spatial differentiation the rainfall data for Britain are presented for the regional divisions of the precursor organisations of the EA and SEPA. Following the discontinuation of The Met Office's CARP system in July 1998, the areal rainfall figures have been derived using several procedures, including initial estimates based on MORECS*. Recent figures have been produced by The Met Office, National Climate Information Centre (NCIC), using a technique similar to CARP. An initiative is underway with The Met Office to provide more accurate areal figures and, since October 1999, to include more raingauges in the analysis. A significant number of additional monthly rainfall totals are currently being provided by the Environment Agencies. As with all regional figures based on limited raingauge networks the monthly tables and accumulations (and the return periods associated with them) should be regarded as a guide only.
*MORECS is the generic name for The Met Office services involving the routine calculation of evaporation and soil moisture throughout Great Britain.
