# Hydrological Summary for the United Kingdom 

## General

June was a month of contrasting weather patterns: a very warm and dry spell brought an arid complexion to the landscape and generated some local concern for the water resources outlook (e.g. in parts of Northern Ireland); subsequently, much more unsettled weather conditions predominated with some significant and damaging storms; these autumnal conditions extended into July. Nationally, the June rainfall total was near-average but spatial variations were large; parts of the English Lowlands were again relatively dry. Reservoir stocks declined briskly through early June and a few impoundments were seasonally low at month end (e.g. Roadford and Silent Valley), but overall stocks for England and Wales were within $1 \%$ of the long term average entering July. River flows exhibited a substantial range with some notably high and notably low summer flows reported - but June runoff totals were mostly typical of the early summer, albeit generally below average. Groundwater level recessions are generally tracking below the seasonal average but - with a few local exceptions - well above drought minima. Medium and longer term rainfall deficiencies remain significant but the water resources outlook for the summer is generally good.

## Rainfall

The unsettled weather of late May continued into June with significant rainfall in northern Britain (Tain Range Highland region- reported 38 mm on the $11^{\text {th }}$ ) but rainfall amounts were very modest in the South and, with high pressure dominating, some localities (e.g. in south Oxfordshire) reported $<1 \mathrm{~mm}$ of rainfall up to the $19^{\text {th }}$. The resulting stress for farmers, growers and gardeners was relieved locally by thunderstorms (e.g. Leconfield reported 23 mm on the $8^{\text {th }}$ ) and, more generally, on the $22 / 23^{\text {rd }}$ when an unusually vigorous summer depression generated rainfall of $15-25 \mathrm{~mm}$ across much of the UK - triggering local flooding and landslides (e.g. in Cornwall); Lough Fea (NI) reported 45 mm and Buxton 46 mm on the following day. The showery nature of much of the rainfall makes for imprecise areal assessments but a notable north-south contrast in June totals is clearly evident. A few localities near the Moray coast reached $300 \%$ of average and above average rainfall was particularly welcome in Northern Ireland. Much of the English Lowlands, however, reported $<50 \%$ with several coastal pockets being extremely dry (e.g. Portsmouth, Southend). In some regions this arid interlude appreciably increased medium term rainfall deficiencies. The February-June period was the $2^{\text {nd }}$ driest in the last 20 years in parts of the South-West, and, for a few southern catchments (e.g. in the Thames basin), above average rainfall has been registered in only 3 or 4 of the last 17 months.

## River Flow

Exceptionally dry soil conditions greatly limited the effectiveness of the early June rainfall and flows in most rivers exhibited steep recessions - a new minimum June flow was recorded for the Ribble (on the $15^{\text {th }}$ ) and a number of flow augmentation schemes were activated (e.g. in south Wessex). By contrast, some localised - mostly urban flooding was reported and more notable flow recoveries characterised the final week of the month. The River Whiteadder eclipsed its previous maximum June flow on the $24^{\text {th }}$ having closely approached its minimum in the second week. South of the Moray Firth, a 48-hr rainfall
total of 80.4 mm (at Torwinny) triggered serious flooding in Elgin and Rothes on the $23 / 24^{\text {th }}-$ precautionary evacuations were organised and the main InvernessAberdeen railway was closed. The Isla at Grange reported its $3{ }^{\text {rd }}$ highest level in a $44-\mathrm{yr}$ record. Grampian Region suffered flash flooding as 14 mm of rain fell in 30 minutes at Kinloss (a 1 -hr total of 16 mm was recorded three days later). June runoff totals showed very wide regional and more local variations. In northern Scotland, the River Naver registered its highest June runoff in a $27-\mathrm{yr}$ record whilst notably low runoff characterised much of south-western Britain; in South Wales, the River Tawe reported its lowest June runoff since 1975. In the English Lowlands, geological control on flows rates was very evident; flows in many Chalk catchments were near-average whilst neighbouring streams draining impermeable catchments reported $<35 \%$ of the June average. Most June runoff totals were in the $50-85 \%$ range, but generally well above drought minima.

## Groundwater

Soil moisture deficits increased rapidly in the first half of June and, notwithstanding the unsettled final week, end-of-month values remained considerably above average in southern Britain. Consequently, little or no infiltration occurred in the major aquifer outcrop areas. After modest late spring infiltration moderated the seasonal decline in the more responsive aquifers, groundwater level recessions re-established themselves in June. By monthend levels were in decline in all but the slowest-responding aquifer units. June levels in the Chalk show significant regional differences but, Killyglen apart, most index well levels remain within the normal early summer range. A similar generalisation applies to the major limestone and Permo-Triassic sandstones outcrops, but levels in the latter are relatively depressed in the Midlands (e.g. at Weeford Flats) and in the most northerly outcrops. Levels remain a little above average in the minor aquifers of eastern England. In the absence of an exceptionally dry late summer and early autumn (as occurred last year), a normal recession pattern is expected to continue.

## Rainfall . . . Rainfall . .

## Key

| 00\% | Percentage of 1961-90 average | Normal range |
| :---: | :---: | :---: |
|  | Very wet | Below average |
|  | Substantially above average | Substantially below average |
|  | Above average | Exceptionally low rainfall |

February 2004 - June 2004
August 2003 - June 2004

## Rainfall accumulation maps

Echoes of the 2003 drought are still evident in the longer term regional rainfall accumulations for most regions. The August 2003 - June 2004 rainfall is the second lowest (after 1996) since 1975/76 for the UK as a whole with the most notable deficiencies in parts of eastern Scotland, Northern Ireland, and the South-West. The latter region also has the highest percentage rainfall deficiency over the last five months.

## River flows - June 2004

*Comparisons based on percentage flows alone can be misleading. A given percentage flow can represent extreme drought conditions in permeable catchments where flow patterns are relatively stable but be well within the normal range in impermeable catchments where the natural variation in flows is much greater. Note: the period of record on which these percentages are based varies from station to station. Percentages may be omitted where flows are under review.

## River flow . . . River flow

## Monthly river flow hydrographs

The river flow hydrographs show the monthly mean flow (bold trace), the long term average monthly flow (dotted trace) and the maximum and minimum flow prior to 2001 (shown by the shaded areas). Monthly flows falling outside the maximum/ minimum range are indicated where the bold trace enters the shaded areas.

## River flow . . . River flow

Notable runoff accumulations (a) May 2004 - June 2004, (b) February 2003 - June 2004

## Groundwater . . . Groundwater

Groundwater levels normally rise and fall with the seasons, reaching a peak in the spring following replenishment through the winter (when evaporation losses are low and soil moist). They decline through the summer and early autumn. This seasonal variation is much reduced when the aquifer is confined below overlying impermeable strata. The monthly max., min. and mean levels are displayed in a similar style to the river flow hydrographs. Note that most groundwater levels are not measured continuously - the latest recorded levels are listed overleaf.

## Groundwater. . . Groundwater

## Groundwater levels - June 2004

The rankings are based on a comparison between the average level in the featured month (but often only single readings are available) and the average level in each corresponding month on record. They need to be interpreted with caution especially when groundwater levels are changing rapidly or when comparing wells with very different periods of record. Rankings may be omitted where they are considered misleading.
Notes: i. The outcrop areas are coloured according to British Geological Survey conventions.
ii. The Newbridge borehole supercedes Redbank (which was affected by groundwater abstraction). Yew Tree Farm levels are now received quarterly.

## Reservoirs . . . Reservoirs

## Guide to the variation in overall reservoir stocks for England and Wales

# National Hydrological Monitoring Programme 

The National Hydrological Monitoring Programme was instigated in 1988 and is undertaken jointly by the Centre for Ecology and Hydrology Wallingford (formerly the Institute of Hydrology - IH) and the British Geological Survey (BGS). Financial support for the production of the monthly Hydrological Summaries is provided by the Department for Environment, Food and Rural Affairs (Defra), the Environment Agency (EA), the Scottish Environment Protection Agency (SEPA), the Rivers Agency (RA) in Northern Ireland, and the Office of Water Services (OFWAT).

## Data Sources

River flow and groundwater level data are provided by the Environment Agency, the Environment Agency Wales, the Scottish Environment Protection Agency and, for Northern Ireland, the Rivers Agency and the Department of the Environment (NI). In all cases the data are subject to revision following validation (flood and drought data in particular may be subject to significant revision).

Reservoir level information is provided by the Water Service Companies, the EA, Scottish Water and the Northern Ireland Water Service.

The National River Flow Archive (maintained by CEH Wallingford) and the National Groundwater Level Archive (maintained by BGS) provide the historical perspective within which to examine contemporary hydrological conditions.

## Rainfall

Most rainfall data are provided by The Met Office (see opposite). To allow better spatial differentiation the rainfall data for Britain are presented for the regional divisions of the precursor organisations of the EA and SEPA. Following the discontinuation of The Met Office's CARP system in July 1998, the areal rainfall figures have been derived using several procedures, including initial estimates based on MORECS*. Recent figures have been produced by The Met Office, National Climate Information Centre (NCIC), using a technique similar to CARP. An initiative is underway with The Met Office to provide more accurate areal figures and, since October 1999, to include more raingauges in the analysis. A significant number of additional monthly rainfall totals are currently being provided by the Environment Agencies. As with all regional figures based on limited raingauge networks the monthly tables and accumulations (and the return periods associated with them) should be regarded as a guide only.
*MORECS is the generic name for The Met Office services involving the routine calculation of evaporation and soil moisture throughout Great Britain.
