# Hydrological Summary for the United Kingdom 

## General

January was notable for an exceptional range of weather conditions - very mild interludes punctuating lengthier cold spells with damaging blizzards on occasions. For the UK as a whole, precipitation was very close to the January average but hydrological conditions were more a reflection of very high antecedent wetness and a few notable storm events accounting for the bulk of the January rainfall total. Accordingly, river flows displayed wide temporal variations through a month which began with remarkably high flows, and extensive flooding, across much of southern Britain in a few catchments flows were the highest since the very widespread flooding in March 1947. The continuing need to provide flood alleviation storage constrained increases in reservoir stocks in some areas but for England Wales as a whole, stocks remain very healthy - around $5 \%$ below capacity. Similarly, groundwater levels approached seasonal maxima throughout many major aquifer units in January. Echoing early 2001, groundwater flooding was experienced in some chalk outcrop areas - signalling both the exceptional health of groundwater resources, and the continuing risk of flooding (both surface and groundwater).

## Rainfall

Contrasting synoptic patterns during January produced airflows across the British Isles from many points of the compass - resulting in large and abrupt temperature changes, and a very uneven distribution of precipitation. In some southern areas $>65 \%$ of the January total fell on the first and last days. Snow constituted a significant proportion of the total in parts of northern Britain (in eastern Scotland especially) and London had appreciable falls on the $8^{\text {th }}$ and $30^{\text {th }}$ - the latter associated with massive transport disruption. Of greater hydrological significance was the continuation of a very wet spell in late December. Some localities in central southern England reported the equivalent of 6-8 weeks of average winter rainfall over the 12 days beginning on the $21 / 12$. Widespread rainfall on New Year's Day - Culdrose (Cornwall) reported 48 mm in 24 hrs - ensured that the, already notable, flooding would become more extensive and protracted. Subsequently, the relative infrequency of westerly frontal systems resulted in generally below average January rainfall totals in the west - parts of Cornwall recorded $<60 \%$ whilst much of eastern England registered well above average totals, approaching $200 \%$ in parts of East Anglia. Much of northern Scotland was also wet, but rainfall deficiencies which began in the late summer of 2002 - continue to build in some western catchments and islands. By contrast, rainfall over the Oct. 2002-Jan. 2003 period exceeds $150 \%$ of the 1961-90 average in a zone from Anglia to Wessex and the 4 -month total for England and Wales ranks $4^{\text {th }}$ highest in the 237-year national series.

## River Flow

2003 began dramatically with many rivers exercising a natural right of dominion over their floodplains. Flows exceeded bankfull in many catchments and flood warnings (peaking at $>300$ on the $2^{\text {nd }}$ ) applied across much of the river network in southern Britain - affecting many localities that were also flooded in late 2000. The Dorset Stour recorded its highest Jan. flow on record and some previous maxima were eclipsed (e.g. on the Thame in Oxfordshire). Over 450 properties were flooded in the Thames Valley as the river - in its middle reaches - reached it highest level
since the snowmelt flood of March 1947. Locally, flood risks were exacerbated by drainage problems and direct runoff from farmland. However, given the antecedent rainfall and the magnitude of the peak flows, flooding of properties was relatively modest. Nonetheless, the onset of anticyclonic conditions provided a very welcome respite, heralding sustained recessions in most rivers. In permeable eastern and southern catchments, these were partly compensated for by rapidly rising baseflow contributions which helped ensure well above average January runoff totals across the English Lowlands particularly in East Anglia and Thames regions (river establishing new max. January flows included the Little Ouse and Kennet). By contrast, runoff in most western and northern catchments (where frozen conditions resulted in very low flows in mid-month) was below average, albeit well within the normal winter range.

## Groundwater

High pressure throughout the two weeks from the $3^{\text {rd }}$ January produced the longest spell without significant infiltration since September in some lowland outcrop areas. Nonetheless, with catchments saturated and rainfall (for the 7 th $^{\text {th }}$ successive month in some areas) broadly favouring the eastern outcrop areas, January infiltration totals exceeded the average throughout most major aquifers - a few western Permo-Triassic sandstones outcrops excepted. But levels in all but the most responsive aquifers reflect infiltration rates over several months (at least) and, since September, infiltration has exceeded twice the average over a significant proportion of the eastern Chalk (e.g. in parts of the North Downs and Chilterns). Since 1960 , only in late 2000 has there been an appreciably more abundant autumn/early winter recharge episode. The impact of the two recent exceptional episodes is evident in the groundwater level hydrographs. January levels in most Chalk outcrop areas were close to seasonal maxima, and unprecedented in some areas (e.g. parts of the Yorkshire Wolds and at Rockley). Levels are generally notably high in most of the (more responsive) limestone outcrops and still exceed pre-2000 maxima in a few parts of the Permo-Triassic sandstones (e.g. Llanfair DC).

## Rainfall accumulation maps

The UK rainfall total for the last four months ranks (provisionally) as the 10th highest in the last 60 years - partly as a result of the notable wetness of much of the English Lowlands; the corresponding total for the Thames catchment is the fourth highest in a series from 1883. For many lowland catchments January was the sixth wet month in the last seven. In stark contrast, the Highland Region in Scotland registered its first above average monthly total since July last year - and parts of western Scotland (e.g. Mull) were again relatively dry).

## River flow . . . River flow

## River flows - January 2003

*Comparisons based on percentage flows alone can be misleading. A given percentage flow can represent extreme drought conditions in permeable catchments where flow patterns are relatively stable but be well within the normal range in impermeable catchments where the natural variation in flows is much greater. Note: the period of record on which these percentages are based varies from station to station.

## River flow . . . River flow

## Monthly river flow hydrographs

The river flow hydrographs show the monthly mean flow (bold trace), the long term average monthly flow (dotted trace) and the maximum and minimum flow prior to 2000 (shown by the shaded areas). Monthly flows falling outside the maximum/ minimum range are indicated where the bold trace enters the shaded areas.

## River flow . . . River flow

Notable runoff accumulations (a) October 2002-January 2003, (b) July 2002 - January 2003

## Groundwater . . . Groundwater

Groundwater levels normally rise and fall with the seasons, reaching a peak in the spring following replenishment through the winter (when evaporation losses are low and soil moist). They decline through the summer and early autumn. This seasonal variation is much reduced when the aquifer is confined below overlying impermeable strata. The monthly max., min. and mean levels are displayed in a similar style to the river flow hydrographs. Note that most groundwater levels are not measured continuously - the latest recorded levels are listed overleaf.

## Groundwater. . . Groundwater

## Groundwater levels - January 2003

The rankings are based on a comparison between the average level in the featured month (but often only single readings are available) and the average level in each corresponding month on record. They need to be interpreted with caution especially when groundwater levels are changing rapidly or when comparing wells with very different periods of record. Rankings may be omitted where they are considered misleading.
(Note: Redbank is affected by groundwater abstraction.)

Details of the individual reservoirs in each of the groupings listed above are available on request. The featured reservoirs may not be representative of the storage conditions across each region; this can be particularly important during droughts. The minimum storage figures relate to the 1988-2003 period only (except for West of Scotland and Northern Ireland where data commence in the mid-1990's). In some gravity-fed reservoirs (e.g. Clywedog) stocks are kept below capacity during the winter to provide scope for flood attenuation purposes.

## Location map . . . Location map

## National Hydrological <br> Monitoring <br> Programme

The National Hydrological Monitoring Programme was instigated in 1988 and is undertaken jointly by the Centre for Ecology and Hydrology, Wallingford (formerly the Institute of Hydrology - IH) and the British Geological Survey (BGS). Financial support for the production of the monthly Hydrological Summaries is provided by the Department for Environment, Food and Rural Affairs (DEFRA), the Environment Agency (EA), the Scottish Environment Protection Agency (SEPA), the Rivers Agency (RA) in Northern Ireland, and the Office of Water Services (OFWAT).

## Data Sources

River flow and groundwater level data are provided by the regional divisions of the EA (England and Wales) and SEPA (Scotland), data for Northern Ireland are provided by the Rivers Agency and the Department of the Environment (NI). In all cases the data are subject to revision following validation (flood and drought data in particular may be subject to significant revision).

Reservoir level information is provided by the Water Service Companies, the EA, Scottish Water and the Northern Ireland Water Service.

The National River Flow Archive (maintained by CEH Wallingford) and the National Groundwater Level Archive (maintained by BGS) provide the historical perspective within which to examine contemporary hydrological conditions.

## Rainfall

Most rainfall data are provided by The Met Office (address opposite). To allow better spatial differentiation the rainfall data for Britain are presented for the regional divisions of the precursor organisations of the EA and SEPA. Following the discontinuation of The Met Office's CARP system in July 1998, the areal rainfall figures have been derived using several procedures, including initial estimates based on MORECS*. Recent figures have been produced by The Met Office, National Climate Information Centre (NCIC), using a technique similar to CARP. An initiative is underway with The Met Office to provide more accurate areal figures and, since October 1999, to include more raingauges in the analysis. A significant number of additional monthly rainfall totals are currently being provided by the Environment Agencies; over the coming months further monthly raingauge totals will be included for selected regions. Until the access to these additional data has stabilised the regional figures (and the return periods associated with them) should be regarded as a guide only.
*MORECS is the generic name for the Meteorological Office services involving the routine calculation of evaporation and soil moisture throughout Great Britain.
