# Hydrological Summary for the United Kingdom 

## General

Weather conditions during February contrasted with those which typified most of the late autumn and early winter. With high pressure dominant the rainfall total for the UK was, provisionally, the second lowest - for February - in the last 18 years. Across most of the country the risk of flooding declined as sustained recessions characterised most river basins. Flood drawdown releases made a minor contribution to a significant reduction in overall reservoir stocks over

## Rainfall

the month, but they remain very close to the late winter average for England and Wales as a whole; with few exceptions, stocks in major impoundments currently exceed $90 \%$ of capacity. Though generally in decline from the January peaks, groundwater levels in most major aquifers remain well above average. The healthy water resources outlook is a reflection of the abundant rainfall (and recharge) over the autumn and early winter. Considerable early March rainfall generally eliminated modest soil moisture deficits - and provided a reminder that most catchments are likely to remain vulnerable to substantial rainfall well into the spring.

February was a dry, sunny month with many areas experiencing a notably wide range of temperatures; an unusual weather combination in the context of the preceding run of months. The infrequency of rain-bearing frontal systems resulted in below average precipitation across much the greater part of the UK. Damaging blizzards (e.g. on the $3^{\text {rd }}$ ) - with substantial snow accumulations - produced considerable transport disruption in Scotland. However precipitation totals were influenced more by the preponderance of dry days in midmonth; many areas reported little more than a trace of rain over the fortnight beginning on the $11^{\text {th }}$. A few localities (e.g. Milford Haven and Morecambe) reported marginally above average February rainfall but most catchments registered between $40 \%$ and $70 \%$ of average; parts of eastern Scotland were especially dry. Provisionally GB registered its third lowest rainfall total in the last 43 months. A continuation of a notable longer term rainfall deficiency in the north and west, contributed to the second lowest winter (Dec-Feb) rainfall total for Scotland since 1964. To the south, winter rainfall totals for all regions were within the normal range, but above average rainfall again characterised much of the English lowlands - many catchments reported their fifth successive wet winter. Western and northern Scotland aside, regional rainfall accumulations over the last 12 months are also above average - notably so for Thames and East Anglia; Northern Ireland is also relatively wet in this timeframe.

## River FIow

In contrast to the exceptional flows - and associated high flood risk - that typified many rivers earlier in the winter, February saw recessions extending throughout most of the month - but with steep recoveries around month-end in many basins. February runoff totals displayed a clear distinction between the responsive, impermeable catchments in the west and north and baseflow-dominated rivers in the English Lowlands. In the former, February mean flows were well below normal - some Scottish and Welsh rivers registering only around $50 \%$ of average. Similarly modest runoff typified a few impermeable lowland
catchments but spring-fed rivers - benefiting from the exceptional groundwater recharge earlier in the winter remained close to seasonal maxima. Relative to the longterm average there was a strong SE/NW gradient in runoff for the winter as a whole. In western Scotland the river Nevis registered its second lowest Dec-Feb runoff on record, whilst the Stringside and Little Ouse (in East Anglia) recording new maximum winter runoff totals. In many more chalk streams the winter runoff ranks second only to 2000/01; over the last three winters runoff has typically exceeded the preceding average by $50 \%$ or more - corresponding to a substantial redefinition of the high flow regime at many gauging stations.

## Groundwater

Rainfall was below 50\% of the February average across large parts of the Chalk outcrop and the dry, mild spell in mid-month saw modest soil moisture deficits established in some eastern and southern areas. Infiltration rates were well below average for February - typically $25-50 \%$ of average - helping to avoid a repeat of the extensive groundwater flooding in early 2001 when late-winter watertables reached the surface in many 'dry' valleys. Significant declines in groundwater levels were reported for a number of the more responsive Chalk wells and boreholes in February (e.g.Chilgrove and Rockley); nonetheless, levels remain notably high (Killyglen in Northern Ireland remains an exception). In many slowerresponding wells (e.g. Therfield), levels are still rising and exceed pre-2000 February maxima in some areas, including the Chilterns. Levels in the Middle Jurassic of the Cotswolds have fallen to within the normal range but in most limestone outcrops, late-winter levels are close to seasonal maxima. Spatial variability is considerable across the Permo-Triassic sandstone outcrops but, aside from wells affected by abstraction (e.g. Redbank), levels remain high - exceptionally so for some index wells in North Wales, the North-West and the Midlands. The early March rainfall has arrested the development of soil moisture deficits but the length of the 2002/03 recharge season will be heavily dependant on rainfall over the next $4-6$ weeks.

Below average

Substantially below average

Exceptionally low rainfall

December 2002 - February 2003
September 2002 - February 2003

## Rainfall accumulation maps

The wet December helped ensure the winter rainfall total for England and Wales was again above average - for the sixth successive year (although the average was only marginally exceeded in a couple of the winters). Like Scotland, Northern Ireland was relatively dry, provisionally the Dec-Feb rainfall total was the second lowest since 1985. Over the six-month timespan, rainfall was exceptionally low in much of northern and western Scotland; for the Highland Region the Sep-Feb total was the lowest in the 27-year regional series.

## River flow . . . River flow

## River flows - February 2003

*Comparisons based on percentage flows alone can be misleading. A given percentage flow can represent extreme drought conditions in permeable catchments where flow patterns are relatively stable but be well within the normal range in impermeable catchments where the natural variation in flows is much greater. Note: the period of record on which these percentages are based varies from station to station.

## River flow <br> River flow

## Monthly river flow hydrographs

The river flow hydrographs show the monthly mean flow (bold trace), the long term average monthly flow (dotted trace) and the maximum and minimum flow prior to 2000 (shown by the shaded areas). Monthly flows falling outside the maximum/ minimum range are indicated where the bold trace enters the shaded areas.

| Kennet | 177 | $40 / 41$ |
| Mole | 166 | $27 / 28$ |

## Groundwater . . . Groundwater

Groundwater levels normally rise and fall with the seasons, reaching a peak in the spring following replenishment through the winter (when evaporation losses are low and soil moist). They decline through the summer and early autumn. This seasonal variation is much reduced when the aquifer is confined below overlying impermeable strata. The monthly max., min. and mean levels are displayed in a similar style to the river flow hydrographs. Note that most groundwater levels are not measured continuously - the latest recorded levels are listed overleaf.

## Groundwater. . . Groundwater

## Groundwater levels - February 2003

The rankings are based on a comparison between the average level in the featured month (but often only single readings are available) and the average level in each corresponding month on record. They need to be interpreted with caution especially when groundwater levels are changing rapidly or when comparing wells with very different periods of record. Rankings may be omitted where they are considered misleading.
(Note: Redbank is affected by groundwater abstraction.)

## Guide to the variation in overall reservoir stocks for England and Wales

| () figures in parentheses relate to gross storage - denotes reservoir groups |  |  |  | +excludes Lough Neagh |  |  |  | *last occurrence - see footnote |  |  |

Details of the individual reservoirs in each of the groupings listed above are available on request. The featured reservoirs may not be representative of the storage conditions across each region; this can be particularly important during droughts. The minimum storage figures relate to the 1988-2003 period only (except for West of Scotland and Northern Ireland where data commence in the mid-1990's). In some gravity-fed reservoirs (e.g. Clywedog) stocks are kept below capacity during the winter to provide scope for flood attenuation purposes.

# National Hydrological Monitoring Programme 

The National Hydrological Monitoring Programme was instigated in 1988 and is undertaken jointly by the Centre for Ecology and Hydrology, Wallingford (formerly the Institute of Hydrology - IH) and the British Geological Survey (BGS). Financial support for the production of the monthly Hydrological Summaries is provided by the Department for Environment, Food and Rural Affairs (Defra), the Environment Agency (EA), the Scottish Environment Protection Agency (SEPA), the Rivers Agency (RA) in Northern Ireland, and the Office of Water Services (OFWAT).

## Data Sources

River flow and groundwater level data are provided by the regional divisions of the EA (England and Wales) and SEPA (Scotland), data for Northern Ireland are provided by the Rivers Agency and the Department of the Environment (NI). In all cases the data are subject to revision following validation (flood and drought data in particular may be subject to significant revision).

Reservoir level information is provided by the Water Service Companies, the EA, Scottish Water and the Northern Ireland Water Service.

The National River Flow Archive (maintained by CEH Wallingford) and the National Groundwater Level Archive (maintained by BGS) provide the historical perspective within which to examine contemporary hydrological conditions.

## Rainfall

Most rainfall data are provided by The Met Office (address opposite). To allow better spatial differentiation the rainfall data for Britain are presented for the regional divisions of the precursor organisations of the EA and SEPA. Following the discontinuation of The Met Office's CARP system in July 1998, the areal rainfall figures have been derived using several procedures, including initial estimates based on MORECS*. Recent figures have been produced by The Met Office, National Climate Information Centre (NCIC), using a technique similar to CARP. An initiative is underway with The Met Office to provide more accurate areal figures and, since October 1999, to include more raingauges in the analysis. A significant number of additional monthly rainfall totals are currently being provided by the Environment Agencies; over the coming months further monthly raingauge totals will be included for selected regions. Until the access to these additional data has stabilised the regional figures (and the return periods associated with them) should be regarded as a guide only.
*MORECS is the generic name for the Meteorological Office services involving the routine calculation of evaporation and soil moisture throughout Great Britain.

The National Hydrological Monitoring Programme depends on the active cooperation of many data suppliers. This cooperation is gratefully acknowledged.

## Subscription

Subscription to the Hydrological Summaries costs $£ 48$ per year. Orders should be addressed to:

Hydrological Summaries
