# Hydrological Summary for the United Kingdom 

## General

August was an extremely warm month - the $38.1^{\circ} \mathrm{C}$ registered at Gravesend on the 10th established a new UK maximum - and exceptionally low rainfall totals characterised most regions. This arid combination was reflected in the parched landscape, minimal soil moisture, early leaf fall and, in impermeable catchments, depressed river flows with associated ecological stress (e.g. salmon fatalities were reported in the Aberdeenshire Dee). Abstraction restrictions limited replenishment to some pumped storage reservoirs (e.g. Rutland Water) and heat-wave conditions triggered increases in water demand. Overall reservoir stocks (for England \& Wales) registered their second largest monthly decline on record. Nonetheless overall stocks remain within $4 \%$ of the late summer average and well above drought minima in almost all regions. This, together with groundwater levels that are (mostly) within the normal range, has moderated the impact on water resources of a very substantial rainfall deficiency that began early in the year - the provisional UK rainfall total for the Feb-Aug period was the lowest since 1984. The current extremely dry soils are very likely to delay substantially the seasonal recovery of river flows and runoff rates. In the event of a dry autumn, the water resources outlook will require careful monitoring over the coming winter.

## Rainfall

Synoptic patterns during August were dominated by persistent anticyclonic conditions bringing stable, hot and dry weather to almost all of the UK; the few frontal incursions were largely limited to the north-western and southern extremities of Britain. Although the UK's longest absolute drought (73-days in East London in 1893) was not threatened, many notably arid interludes were reported - sequences of 26 or more rainless days being reported in parts of the English Lowlands. A few locally intense storms did occur, e.g. 48 mm in 15 minutes at Carlton-in-Cleveland, ( N . Yorks), and significant rainfall on the 28th prevented existing August rainfall minima being eclipsed in many localities. Nonetheless, August totals were below 20\% of average across the greater part of the UK, and some lowland catchments registered totals of less than 5 mm . Provisional data suggest that August was the third driest (= to 1976) for the UK in a 104-year record. Parts of northeastern Britain aside, summer (June-August) regional rainfall totals were generally well below average but, more significantly from a resources perspective, August was the seventh successive month with below average rainfall in some catchments in the English lowlands. Provisional figures suggest that the Feb-August rainfall was the second lowest in the last 65 years for the Thames Valley - 1976 was substantially drier. Deficiencies in this timeframe are also notable in much of northern England and eastern Scotland.

## River FIow

Some increases in river flow occurred in western catchments towards month end but generally the summer recessions continued and, with natural storage greatly depleted in impermeable catchments, runoff rates were depressed during the second half of August. Daily mean flows were commonly the lowest since the 1995/96 drought and new absolute minimum flows were established for a few rivers (e.g. in the Tweed basin). Abstraction restrictions and other flow support measures were activated to mitigate low flows but, more generally, the benefit of baseflows to
lowland rivers was underlined in many spring-fed rivers where flows remained in the normal range, albeit below average. August runoff totals were particularly depressed across much of northern Britain - the Deveron registered its 2nd lowest August flow in 42-year record - and very low also in some impermeable southern catchments, but generally well above drought minima. This is broadly true for the summer runoff totals also but the Spey, Dee and Whiteadder were among those rivers establishing new minimum June-Aug totals. Many recent droughts (including 1995, 1984 and 1976) have seen significant flow recoveries in the early autumn. Given the current parched condition of the catchments a repetition this year is unlikely. In the absence of exceptional late September rainfall, notably low flows may become very widespread over the coming weeks.

## Groundwater

Soil Moisture Deficits in late August were exceptionally high - commonly $30-40 \mathrm{~mm}$ above the average for the end of summer (and unprecedented in a few areas - e.g. in eastern Scotland). As usual, many of the highest late summer deficiencies coincided with the outcrop areas of the major aquifers. Correspondingly, the summer groundwater level recessions continued leaving levels particularly depressed in parts of the southern Chalk - at Compton (in the South Downs) lower August levels have only been recorded during the 1976 drought - in a series extending back to 1894. Levels are also low in NI but throughout the greater part of the Chalk outcrop they are within the normal late summer range. Levels in the limestone aquifers are also within the normal range but considerably below average whilst levels remain healthy throughout the Permo-Triassic sandstones outcrops (note: Redbank is affected by groundwater abstraction). But given current smds - the equivalent of $>12$ weeks residual rainfall in some eastern areas - further declines are inevitable; even average rainfall would not generate significant recoveries before the early winter in many eastern outcrops.

Below average

Substantially below average

Exceptionally low rainfall

June 2003 - August 2003
February 2003 - August 2003

## Rainfall accumulation maps

Summer (June-August) rainfall totals were well below average in most regions, and particularly in north-eastern Scotland which had its second driest summer (after 1976) in at least 40 years. In the 7 -month timeframe the regional rainfall deficiencies are generally more exceptional with notable droughts established across much of north-eastern and southeastern Britain.

## River flow . . . River flow

## River flows - August 2003

*Comparisons based on percentage flows alone can be misleading. A given percentage flow can represent extreme drought conditions in permeable catchments where flow patterns are relatively stable but be well within the normal range in impermeable catchments where the natural variation in flows is much greater. Note: the period of record on which these percentages are based varies from station to station. Percentages may be omitted where flows are under review.

## River flow . . . River flow

## Monthly river flow hydrographs

The river flow hydrographs show the monthly mean flow (bold trace), the long term average monthly flow (dotted trace) and the maximum and minimum flow prior to 2000 (shown by the shaded areas). Monthly flows falling outside the maximum/ minimum range are indicated where the bold trace enters the shaded areas.

## River flow . . . River flow

Notable runoff accumulations (a) August 2003, (b) June 2003 - August 2003, (c) February 2003 - August 2003

## Groundwater . . . Groundwater

Groundwater levels normally rise and fall with the seasons, reaching a peak in the spring following replenishment through the winter (when evaporation losses are low and soil moist). They decline through the summer and early autumn. This seasonal variation is much reduced when the aquifer is confined below overlying impermeable strata. The monthly max., min. and mean levels are displayed in a similar style to the river flow hydrographs. Note that most groundwater levels are not measured continuously - the latest recorded levels are listed overleaf.

## Groundwater. . . Groundwater

## Groundwater levels - August 2003

The rankings are based on a comparison between the average level in the featured month (but often only single readings are available) and the average level in each corresponding month on record. They need to be interpreted with caution especially when groundwater levels are changing rapidly or when comparing wells with very different periods of record. Rankings may be omitted where they are considered misleading.
(Note: Redbank is affected by groundwater abstraction.)

## Reservoirs . . . Reservoirs

| () figures in parentheses relate to gross storage - denotes reservoir groups |  |  |  | +excludes Lough Neagh |  |  |  | *last occurrence - see footnote |  |  |

Details of the individual reservoirs in each of the groupings listed above are available on request. The featured reservoirs may not be representative of the storage conditions across each region; this can be particularly important during droughts. The storage figures relate to the 1988-2003 period only (except for West of Scotland and Northern Ireland where data commence in the mid-1990's). In some gravity-fed reservoirs (e.g. Clywedog) stocks are kept below capacity during the winter to provide scope for flood attenuation purposes.

## Location map . . . Location map

# National Hydrological Monitoring Programme 

The National Hydrological Monitoring Programme was instigated in 1988 and is undertaken jointly by the Centre for Ecology and Hydrology, Wallingford (formerly the Institute of Hydrology - IH) and the British Geological Survey (BGS). Financial support for the production of the monthly Hydrological Summaries is provided by the Department for Environment, Food and Rural Affairs (Defra), the Environment Agency (EA), the Scottish Environment Protection Agency (SEPA), the Rivers Agency (RA) in Northern Ireland, and the Office of Water Services (OFWAT).

## Data Sources

River flow and groundwater level data are provided by the Environment Agency, the Environment Agency Wales, the Scottish Environment Protection Agency and, for Northern Ireland, the Rivers Agency and the Department of the Environment (NI). In all cases the data are subject to revision following validation (flood and drought data in particular may be subject to significant revision).

Reservoir level information is provided by the Water Service Companies, the EA, Scottish Water and the Northern Ireland Water Service.

The National River Flow Archive (maintained by CEH Wallingford) and the National Groundwater Level Archive (maintained by BGS) provide the historical perspective within which to examine contemporary hydrological conditions.

## Rainfall

Most rainfall data are provided by The Met Office (see opposite). To allow better spatial differentiation the rainfall data for Britain are presented for the regional divisions of the precursor organisations of the EA and SEPA. Following the discontinuation of The Met Office's CARP system in July 1998, the areal rainfall figures have been derived using several procedures, including initial estimates based on MORECS*. Recent figures have been produced by The Met Office, National Climate Information Centre (NCIC), using a technique similar to CARP. An initiative is underway with The Met Office to provide more accurate areal figures and, since October 1999, to include more raingauges in the analysis. A significant number of additional monthly rainfall totals are currently being provided by the Environment Agencies. As with all regional figures based on limited raingauge networks the monthly tables and accumulations (and the return periods associated with them) should be regarded as a guide only.
*MORECS is the generic name for the Meteorological Office services involving the routine calculation of evaporation and soil moisture throughout Great Britain.
