5 **SUMMARY**

6 The eleventh generation of the International Geomagnetic Reference Field (IGRF) was
 7 adopted in December 2009 by the International Association of Geomagnetism and Aeron-
 8 omy (IAGA) Working Group V-MOD. It updates the previous IGRF generation with a
 9 definitive main field model DGRF 2005.0, for 2005.0, a main field model IGRF 2010.0,
 10 for 2010.0, and a linear predictive secular variation model for 2010.0–2015.0. In this note
 11 the equations defining the IGRF model are provided together with the spherical harmonic
 12 coefficients for the eleventh generation. Maps of the magnetic Declination, Inclination
 13 and Total Intensity for epoch 2010.0 and their predicted rate of change for 2010.0–2015.0
 14 are presented and the recent evolution of the South Atlantic Anomaly and magnetic pole
 15 positions are examined.

16 **Key words:** Geomagnetism – Main Field – Secular Variation – Reference Field – IGRF

17 **1 INTRODUCTION**

18 The International Geomagnetic Reference Field (IGRF) is an established numerical model used to
 19 calculate the large scale, internal, part of the Earth's magnetic field at times between 1900.0 A.D.
 20 and present, at locations on or above Earth's surface. It is produced and maintained by a team of
 21 geomagnetic field modellers under the auspices of the International Association of Geomagnetism and
 22 Aeronomy (IAGA) Working Group V-MOD and is derived from observations collected by satellites, at
 23 magnetic observatories, and during magnetic surveys. It is used by scientists (for example in studies of
 24 space weather or in investigations of local magnetic anomalies) and also by commercial organizations
 25 and private individuals who often use the geomagnetic field as a source of orientation information.

26 The internal part of the geomagnetic field, which is almost entirely core-generated, undergoes
 27 slow, but noticeable, changes over years to decades. Consequently the IGRF must be revised, typically
 28 every five years, in order to remain up to date and as accurate as possible; Table 1 summarizes details
 29 of previous generations of the IGRF. Each generation of the IGRF consists of a series of constituent
 30 models at five-year intervals, each one of which is designated definitive or non-definitive. Once a con-
 31 stituent model is designated definitive it is called a Definitive Geomagnetic Reference Field (DGRF)
 32 and it is not revised in subsequent generations of the IGRF. The non-definitive constituent models
 33 are referred to as IGRFs. Note that DGRFs have been produced only for epochs from 1945.0 on-
 34 wards. For further details concerning the history of the IGRF readers should consult Barton (1997),

Full name	Short name	Valid for	Definitive for	Reference
IGRF 11th generation	IGRF-11	1900.0-2015.0	1945.0-2005.0	Finlay et al. (2010) - this article
IGRF 10th generation	IGRF-10	1900.0-2010.0	1945.0-2000.0	Maus et al. (2005a)
IGRF 9th generation	IGRF-9	1900.0-2005.0	1945.0-2000.0	Macmillan et al. (2003)
IGRF 8th generation	IGRF-8	1900.0-2005.0	1945.0-1990.0	Mandea & Macmillan (2000)
IGRF 7th generation	IGRF-7	1900.0-2000.0	1945.0-1990.0	Barton (1997)
IGRF 6th generation	IGRF-6	1945.0-1995.0	1945.0-1985.0	Langel (1992)
IGRF 5th generation	IGRF-5	1945.0-1990.0	1945.0-1980.0	Langel et al. (1988)
IGRF 4th generation	IGRF-4	1945.0-1990.0	1965.0-1980.0	Barraclough (1987)
IGRF 3rd generation	IGRF-3	1965.0-1985.0	1965.0-1975.0	Peddie (1982)
IGRF 2nd generation	IGRF-2	1955.0-1980.0	–	IAGA (1975)
IGRF 1st generation	IGRF-1	1955.0-1975.0	–	Zmuda (1971)

Table 1. Summary of IGRF generations, their intervals of validity and related references.

35 Maus et al. (2005a) or Macmillan & Finlay (2010); here attention will focus on the latest (11th gen-
 36 eration) revision. Legacy versions of the IGRF are now available from the online archive located at
 37 http://www.ngdc.noaa.gov/IAGA/vmod/igrf_old_models.html. These may be useful, for ex-
 38 ample, to workers who know that a previous generation IGRF had been subtracted from their data and
 39 who wish to recover the original data or re-correct it with a more recent IGRF revision.

40 The 11th generation of the IGRF (hereafter IGRF-11) was agreed in December 2009 by a task
 41 force of IAGA Working Group V-MOD. The purpose of this note is to document the release of IGRF-
 42 11, to act as a permanent published record of model coefficients, and to briefly describe the large scale
 43 features of the present geomagnetic field at Earth’s surface as revealed by the updated model.

44 2 MATHEMATICAL FORMULATION OF THE IGRF MODEL

45 On and above the Earth’s surface, the IGRF model represents the geomagnetic field $\mathbf{B}(r, \theta, \phi, t)$ pro-
 46 duced by internal sources in terms of a scalar potential $V(r, \theta, \phi, t)$. We then have $\mathbf{B} = -\nabla V$ where
 47 V is a finite series having the numerical Gauss coefficients g_n^m, h_n^m (conventionally given in units of
 48 nanotesla, hereafter nT):

$$49 \quad V(r, \theta, \phi, t) = a \sum_{n=1}^N \sum_{m=0}^n \left(\frac{a}{r}\right)^{n+1} [g_n^m(t) \cos m\phi + h_n^m(t) \sin m\phi] P_n^m(\cos \theta). \quad (1)$$

50 Here r denotes the radial distance from the centre of the Earth in units of km, $a = 6371.2$ km is
 51 the magnetic reference spherical radius which is close to the mean Earth radius, θ denotes geocentric

52 co-latitude (i.e. 90° - latitude), and ϕ denotes east longitude. When converting between geocentric and
 53 geodetic co-ordinates, it is recommended to use the World Geodetic System 1984 datum and spheroid
 54 (major axis A of 6378.137 km and a reciprocal flattening $1/f$ of 298.257223563). $P_n^m(\cos \theta)$ are the
 55 Schmidt semi- (or quasi-) normalized associated Legendre functions of degree n and order m (see, for
 56 example, Winch et al., 2005). The maximum spherical harmonic degree of the expansion is N .

57 In the IGRF model, Gauss coefficients g_n^m and h_n^m are provided for the main field (MF) at epochs
 58 separated by 5 year intervals between 1900.0 and 2010.0 A.D. The time-dependence of the Gauss
 59 coefficients is then specified using the following linear expression,

$$60 \quad g_n^m(t) = g_n^m(T_0) + g_n^{im}(T_0) \cdot (t - T_0), \quad (2)$$

61 and similarly for h_n^m . Here t is the time of interest (in units of years) and T_0 is the epoch preceding t
 62 which is an exact multiple of 5 years, such that $T_0 \leq t < (T_0 + 5.0)$. The coefficients $g_n^{im}(T_0)$, given in
 63 units of nT/yr, denote the average first time derivative of $g_n^m(t)$ during the interval T_0 to $T_0 + 5.0$, i.e.
 64 the linear secular variation (SV) during this interval. When MF models exist for both T_0 and $T_0 + 5.0$
 65 then $g_n^{im}(T_0)$ is simply calculated using linear interpolation as $[g_n^m(T_0 + 5.0) - g_n^m(T_0)]/5.0$. For the
 66 final 5 years of the model validity (between 2010.0 and 2015.0 for IGRF-11) coefficients of predictive
 67 average SV $g_n^{im}(t)$ and $h_n^{im}(t)$ are explicitly provided.

68 The geocentric components of the geomagnetic field in the northward, eastward and radially in-
 69 wards directions (X' , Y' and Z') are obtained from the model coefficients using equation (1) and by
 70 taking appropriate components of the gradient of V in spherical polar co-ordinates,

$$71 \quad X' = \frac{1}{r} \frac{\partial V}{\partial \theta}, \quad Y' = -\frac{1}{r \sin \theta} \frac{\partial V}{\partial \phi}, \quad Z' = \frac{\partial V}{\partial r}. \quad (3)$$

72 It is often necessary to work in geodetic co-ordinates and to use the World Geodetic System
 73 1984 datum defined above. Transformations from geocentric to geodetic coordinates and from the
 74 geocentric field components (X' , Y' , Z') into the geodetic field components (X , Y , Z) are described
 75 by eqns 1 - 4 of Hulot et al. (2007). Often the Declination D , Inclination I , the horizontal intensity H
 76 and the total intensity F are required for applications; these are obtained from X , Y and Z using the
 77 relations,

$$78 \quad H = \sqrt{X^2 + Y^2}, \quad F = \sqrt{X^2 + Y^2 + Z^2}, \quad D = \arctan(Y/X), \quad I = \arctan(Z/H). \quad (4)$$

79 The computation of field components from the model coefficients can be performed using the software
 80 available at <http://www.ngdc.noaa.gov/IAGA/vmod/igrf.html> or using the online calculators
 81 listed in section 5.

82 3 THE 11TH GENERATION IGRF

83 In May 2009 the IGRF-11 task force (as appointed by IAGA Division V-MOD) issued a call for can-
 84 didate models. Candidates for the Definitive Geomagnetic Reference Field (DGRF) for epoch 2005,
 85 for a provisional IGRF model for epoch 2010, and for a predictive SV model for the interval 2010-
 86 2015 were requested. Candidates were received in early October 2009. Seven candidates were sub-
 87 mitted for the DGRF epoch 2005.0 and IGRF epoch 2010.0 MF models. Team A was led by DTU
 88 Space, Denmark along with workers from IPGP, France and GSFC-NASA, U.S.A.; Team B was led
 89 by NGDC/NOAA, U.S.A. together with colleagues from GFZ, Germany; Team C was from BGS,
 90 U.K.; Team D was from IZMIRAN, Russia; Team E was led by EOST, France with assistance from
 91 colleagues at LPGN, IPGP and LATMOS, France; Team F was led by IPGP, France with input from
 92 workers in NGDC/NOAA, U.S.A. and LPGN, EOST and LATMOS, France; Team G was from GFZ,
 93 Germany. The same teams also contributed candidate SV models and there was one additional SV
 94 candidate from a team led by GSFC-NASA, U.S.A. in collaboration with UMBC, U.S.A. and Univ.
 95 Liverpool, U.K.; in all, eight SV candidates were received.

96 The MF candidate models had a maximum spherical harmonic degree $N = 13$, while the task
 97 force voted to retain a maximum degree of $N = 8$ for the predictive SV models. The candidate
 98 models together with brief descriptions provided by the authors may be obtained from the web page
 99 <http://www.ngdc.noaa.gov/IAGA/vmod/candidatemodels.html>. Papers providing fuller de-
 100 tails on the candidate models and describing the evaluations carried out by the task force (similar to
 101 the analysis of the candidates contributing to IGRF-10 carried out by Maus et al., 2005b) will appear
 102 in a forthcoming special issue of Earth, Planets and Space.

103 The final IGRF-11 MF models for epochs 2005.0 and 2010.0 as well as the predictive SV model
 104 for 2010.0-2015.0 were calculated using weighted means of the candidates. The weights were agreed
 105 by a vote of the IGRF-11 task force based on information gleaned from various evaluations, fuller
 106 details of which are given in Finlay et al. (2010).

107 High quality, globally distributed, observations of the geomagnetic field are essential to the pro-
 108 duction of an accurate IGRF revision. The collection of the required comprehensive set of observations
 109 involves a significant international collaborative effort. The availability of satellite measurements,
 110 from the CHAMP (Reigber et al., 2002), Ørsted (Neubert et al., 2001) and SAC-C missions, and
 111 observatory measurements (see Table 4 in the Appendix) was of fundamental importance to IGRF-11.

112 IGRF-11 remains unchanged from IGRF-10 for epoch 2000 and earlier. The model MF coeffi-
 113 cients are rounded to 1 nT for epochs between 1900.0 and 1995.0; to 0.1 nT for epochs 2000.0 and
 114 2010.0, and to 0.01 nT for DGRF 2005.0 reflecting the increasing consistency of the candidate models
 115 (Finlay et al., 2010). The predictive SV coefficients are rounded to the nearest 0.1 nT/yr. Note that

116 although the formal root mean square (rms) error in DGRF 2005.0, based on the internal consistency
117 of the contributing candidates, was only 1.0 nT, the true error (due to errors of commission rather
118 than unmodelled sources in the Earth's crust and magnetosphere) is probably closer to 5 nT. The error
119 in IGRF-2010 is expected to be slightly larger (approximately 10 nT) because extrapolation of mod-
120 els from submission in October 2009 forward to 2010 was necessary (Lowes, 2000). Regarding the
121 predictive SV model, retrospective analysis of previous predictions has shown that errors of up to 20
122 nT/yr are likely (Maus et al., 2005b; Finlay et al., 2010). For further details on the limitations of the
123 IGRF and difficulties in estimating its accuracy readers should consult the IGRF health warning found
124 at <http://www.ngdc.noaa.gov/IAGA/vmod/igrfhw.html>.

125 **4 IGRF-11 MODEL COEFFICIENTS AND MAPS**

126 In Table 2 the Schmidt semi-normalized spherical harmonic coefficients comprising IGRF-11 are re-
127 produced. Units are nT for the MF models and nT/yr for the predictive SV model . The coefficients
128 are also available in various file formats at <http://www.ngdc.noaa.gov/IAGA/vmod/igrf.html>,
129 together with software to compute the various components of the magnetic field values. IGRF-11 is
130 also available from the world data centres listed at the end of this paper.

Table 2: 11th Generation International Geomagnetic Reference Field. Here Schmidt semi-normalized spherical harmonic coefficients are provided. Coefficients for degrees n=1,13 in units nanotesla are listed for IGRF and definitive DGRF main-field models. Coefficients for degrees n=1,8 in units of nanotesla/year are listed for the predictive secular variation. Undefined coefficients are marked with '-'; these should be set to 0.0 in numerical calculations as is the case in the coefficient files available online.

132 Maps of the Declination D , Inclination I and Total Intensity F at Earth's surface in 2010 are dis-
 133 played in Figure 1. Together these quantities completely define the vector magnetic field. Noteworthy
 134 features include the fact that there are three agonic lines (lines of zero D), while a more dipolar-type
 135 field would have only two. These correspond to the one that passes approximately north-south through
 136 the Americas, and the one located to the east of Asia continuing down through Indonesia then to the
 137 west of Australia. The extra one passes down through central Europe extending as far south as Kenya
 138 before looping back northward via India. Moreover, D is rather small over a large region spanning
 139 mid and low latitudes extending from northeastern Africa east to the Philippine islands. The map of
 140 I in the middle panel of Figure 1 displays a distinctive deflection in the dip equator southwards at
 141 South America, an offset in the maximum of I from the geographic south pole towards Australia and
 142 also a tongue of high I extending westwards from Southern Africa. The map of F in 2010 in the
 143 bottom panel of Fig. 1 shows that the regions with highest field intensity are located in Siberia in the
 144 northern hemisphere and in the Southern Ocean and Antarctica southwards of Australia in the south-
 145 ern hemisphere. Perhaps the most striking feature of all is the low field intensity anomaly currently
 146 centred around Southern Brazil and Paraguay. This feature is often referred to as the South Atlantic
 147 Anomaly, and it is known to have important consequences regarding the impact of space weather on
 148 the near-Earth electromagnetic environment (Gledhill, 1976; Heirtzler, 2002; Facius & Reitz, 2007).

149 All the features mentioned above are well known from previous global field models; they have ex-
 150 isted for at least several hundred years and have slowly evolved to their present configuration (Jackson
 151 et al., 2000). The current evolution of main field is illustrated in Fig. 2 which shows the IGRF-11 pre-
 152 diction of the average annual rate of change (SV) in the Declination D , Inclination I and Total Intensity
 153 F between 2010 and 2015. The predicted changes in D are small in the Pacific hemisphere, and con-
 154 sistent with a continued westward motion of field features in the Atlantic hemisphere. Changes in I are
 155 predicted to be largest at low latitudes, with the maximum negative change occurring near northeastern
 156 Brazil (close to where the dip equator is presently being deflected southwards) while the maximum
 157 positive change is predicted to occur close to Southern India. Considering the predicted changes in
 158 F , the largest decreases are predicted over eastern North America as well as below South America.
 159 The later involves a continued deepening and westward motion of the South Atlantic Anomaly. The
 160 largest increases in F are predicted to take place in central equatorial Atlantic, in the southern Indian
 161 ocean (southeast of Africa), and in the region encompassing Iran, Kazakhstan, Afghanistan, Pakistan
 162 and India. Understanding of the future evolution of these field features requires detailed knowledge
 163 of the magnetohydrodynamic motional induction processes taking place in the liquid iron outer core.
 164 Such processes are only partly understood at present, but are the focus of much active research (Olson,
 165 2007).

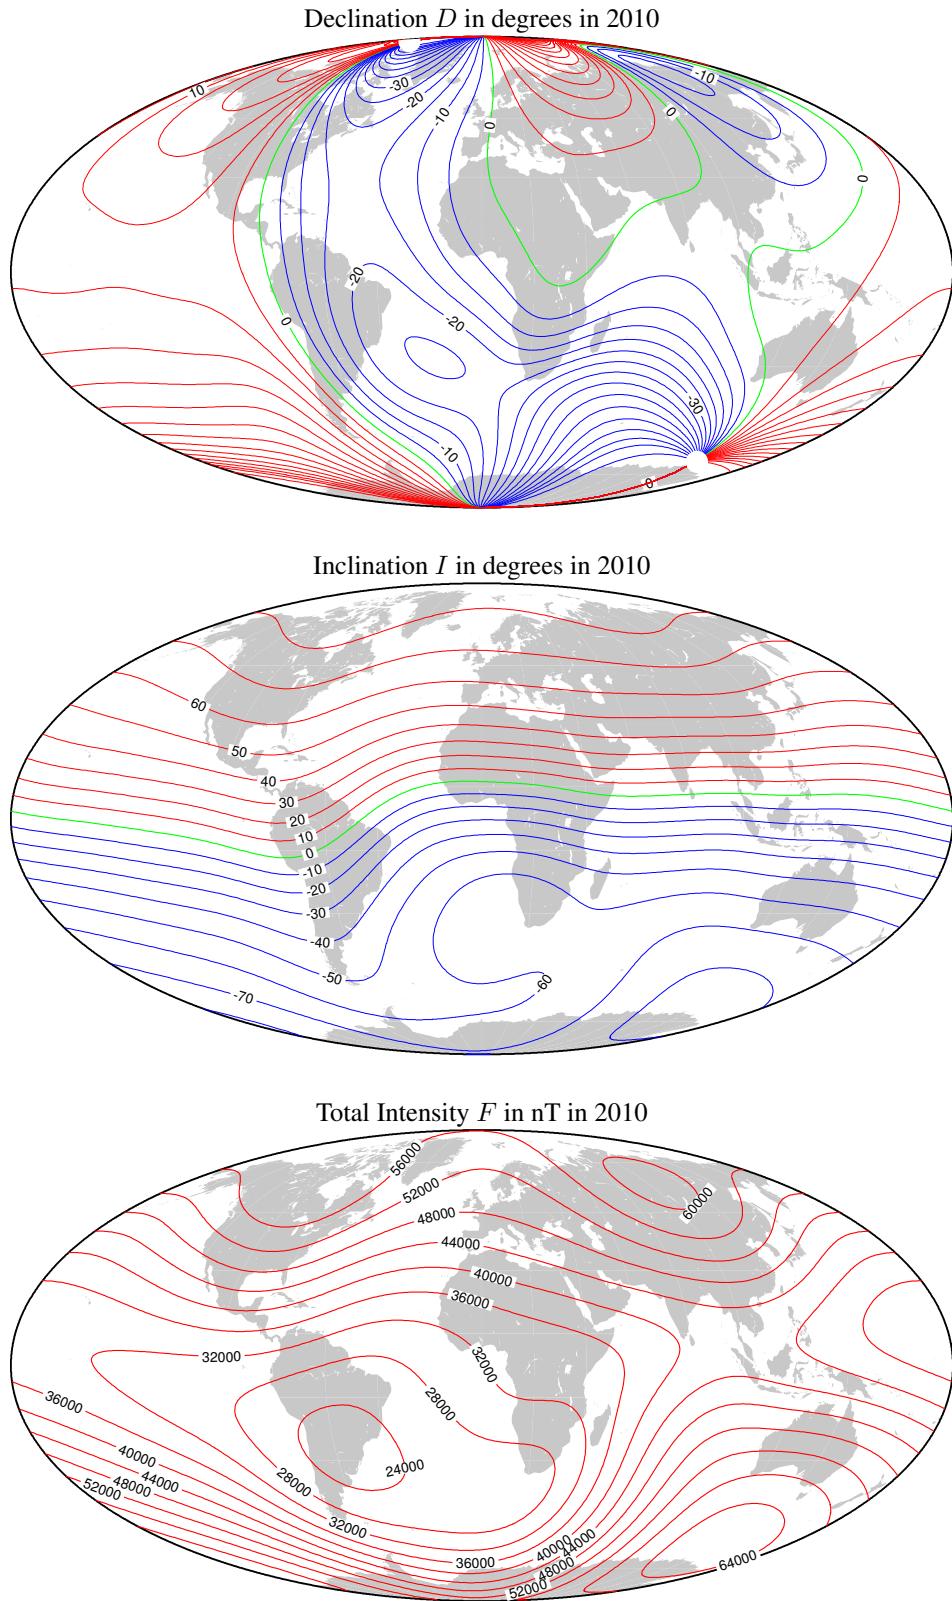

Figure 1. Maps of the magnetic declination D (top, units are degrees), inclination I (middle, units are degrees), and total intensity F (bottom, units are nT) at the Earth's surface in 2010 from the new field model IGRF 2010.0. Mollweide projection is used, zero line is shown in green, positive contours in red and negative contours in blue.

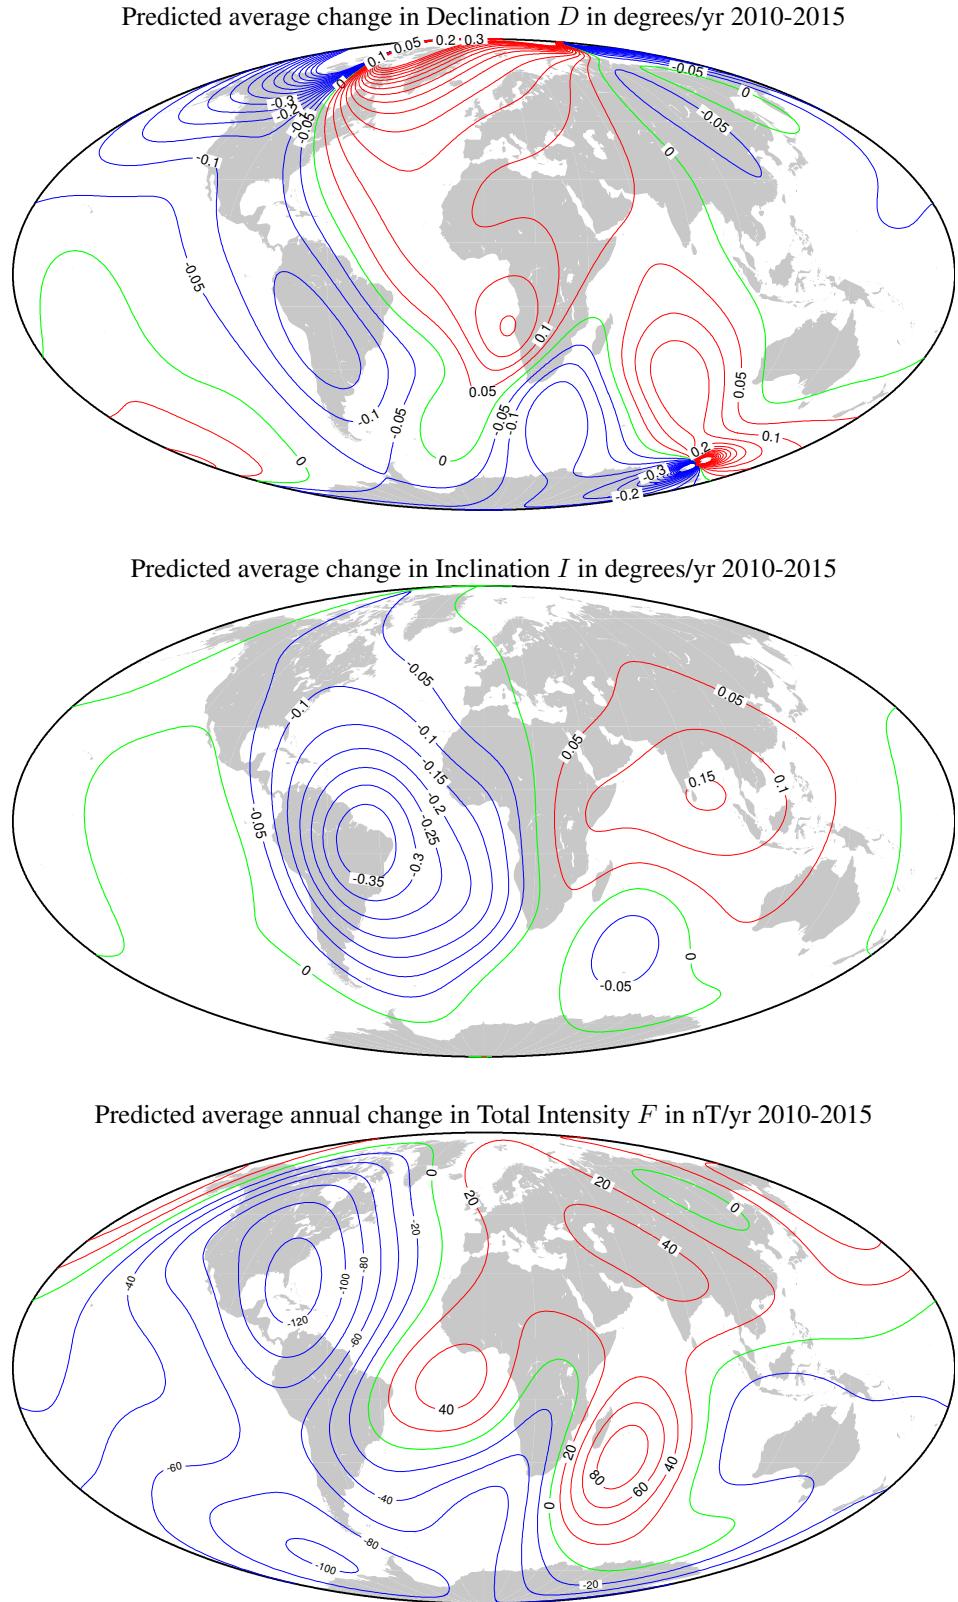

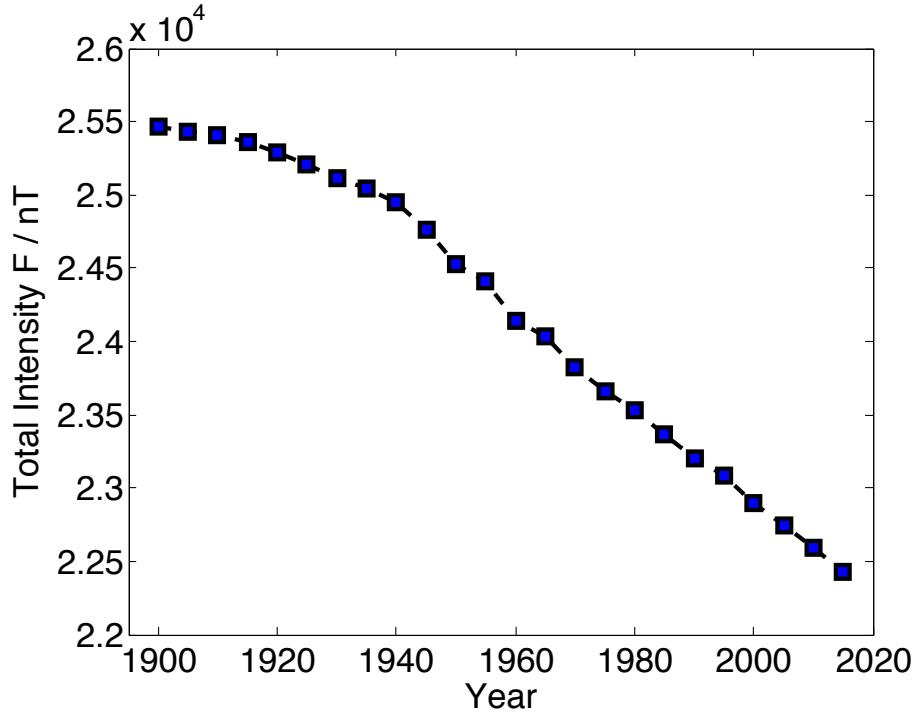

Figure 2. Maps of the predicted rate of change per year in the Declination D (top, units are degrees/yr), the Inclination I (middle, units are degrees/yr), and Total Intensity F (bottom, units are nT/yr) at the Earth's surface for the interval 2010-2015 as predicted by IGRF-11. Mollweide projection is used, zero line is shown in green, positive contours in red and negative contours in blue.

166 Further details concerning the evolution of the South Atlantic Anomaly since 1900 as captured
 167 by IGRF-11 are presented in Fig. 3 (see also Macmillan et al., 2009). The left plot shows how the
 168 lowest field intensity F within the South Atlantic Anomaly has systematically decreased since 1900.
 169 The decrease has been almost linear since 1940 (when the lowest intensity was 24954 nT) until the
 170 present (the lowest intensity in 2010 was 22590 nT) with an average decrease of 34 nT/yr. There is
 171 no sign that the decrease of field intensity in the South Atlantic Anomaly is abating, with a further
 172 decrease to 22430 nT predicted by 2015. The right hand plot documents the motion of the location
 173 of this point of lowest field intensity every 5 years from 1900.0 to 2015.0, where the final point is
 174 a prediction. The position of lowest intensity has moved both southward and westward, but almost
 175 exclusively westwards since 1955. This analysis describes only the position with lowest intensity; the
 176 spatial extent of the south Atlantic anomaly has also increased during the past century, as measured,
 177 for example, by the area within the 28000nT contour of F . Note however, that the exact position of
 178 the lowest intensity point is known only rather crudely, particularly before 1960 when there was larger
 179 uncertainty in the field models.

180 Finally in Fig. 4 we present the positions of the magnetic dip pole (where inclination I as deter-
 181 mined from the complete field model, is vertical) and the geomagnetic pole (as determined only from
 182 the dipole, $n = 1$, field coefficients alone) calculated from IGRF-11 and plotted as a function of time
 183 since 1900. Pole positions are also tabulated in Table 3. It is noteworthy that the North magnetic dip
 184 pole is currently moving at a high speed of over 50 km/yr, as has recently been investigated by Newitt
 185 et al. (2009).

186 Due to the changes currently taking place in the internal geomagnetic field, including the devel-
 187 opment of the South Atlantic Anomaly and the motions of the geomagnetic poles described above,
 188 continued careful monitoring is essential. The CHAMP and Ørsted satellites that were crucial sources
 189 of observations for IGRF-11 are now approaching the end of their lifetimes, but fortunately one of
 190 the aims of the upcoming ESA Swarm mission (Friis-Christensen et al., 2006) is to provide the high
 191 quality satellite data that will be of great importance to the next IGRF revision.

(a)

(b)

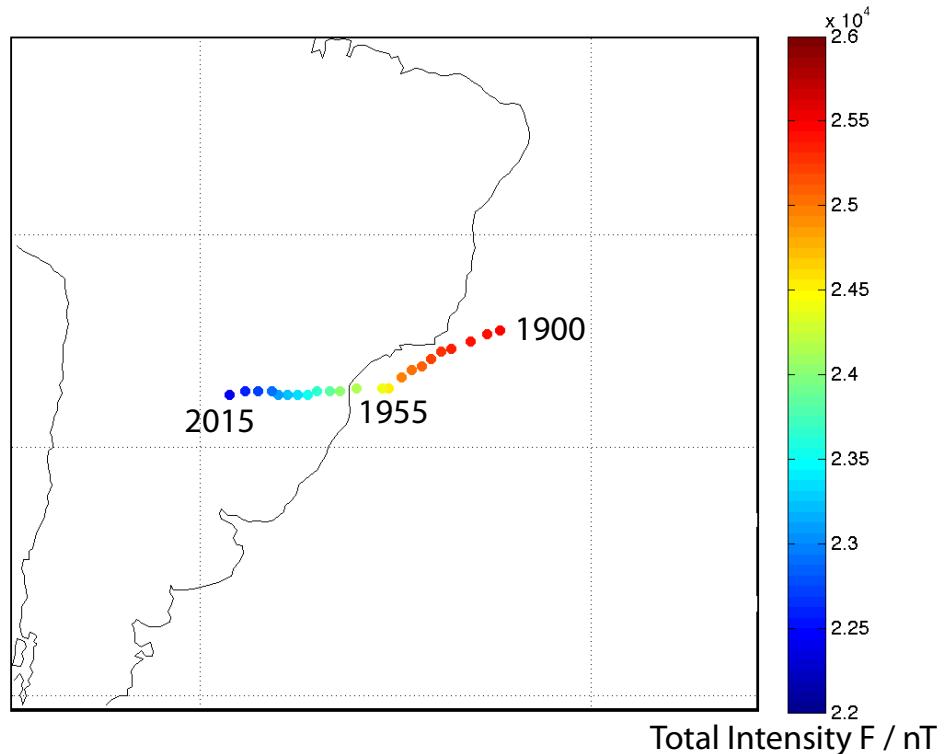

Figure 3. Evolution of the South Atlantic Anomaly during the twentieth century: Top plot (a) shows how the minimum F at the Earth's surface (in the South Atlantic Anomaly where the magnitude of the field is smallest) has decreased from 1900 towards the present day, units are nT . The bottom plot (b) tracks the location of the point of lowest field magnitude with time; the colour scale indicates the magnitude of F , with blue representing smallest F , units are nT .

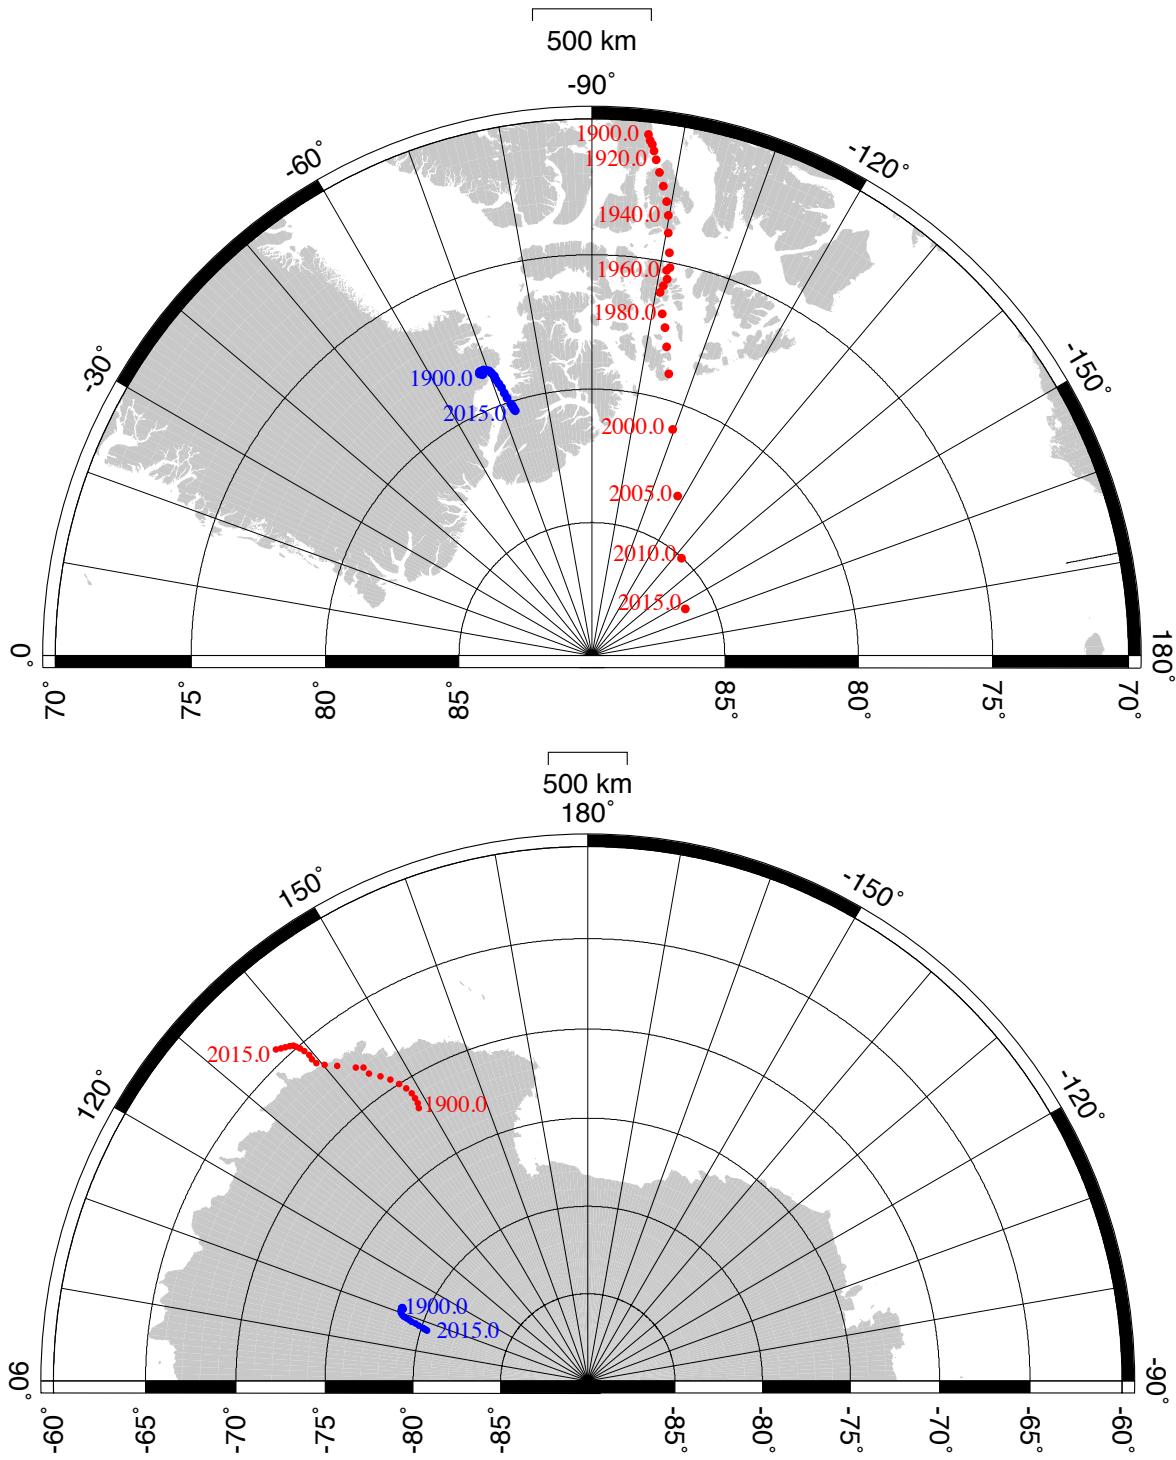

Figure 4. Motion of the magnetic dip pole (red) and geomagnetic pole (blue) since 1900 from IGRF-11 in the northern hemisphere (top) and the southern hemisphere (bottom). Stereographic projection is employed. The scale bar gives an indication of distance that is correct along lines of constant longitude and also along the middle lines of latitude shown (± 80 degrees).

Epoch	North dip pole		South dip pole		North geomagnetic pole		South geomagnetic pole	
	Latitude	Longitude	Latitude	Longitude	Latitude	Longitude	Latitude	Longitude

208

209 Archive of legacy versions of the IGRF model:
210 http://www.ngdc.noaa.gov/IAGA/vmod/igrf_old_models.html

211

212 Candidate models contributing to IGRF-11, and various test models are available for evaluation pur-
213 poses:
214 <http://www.ngdc.noaa.gov/IAGA/vmod/candidatemodels.html>

215

216 The 11th generation IGRF was computed from candidate models produced and evaluated by par-
217 ticipating members of IAGA Working Group V-MOD who are listed as co-authors of this paper. Their
218 institutes and the many organizations involved in operating the magnetic satellites CHAMP, Ørsted
219 and SAC-C, observatories (see Appendix for a list), magnetic survey programmes and the World Data
220 Centres are thanked for their continued support of the IGRF project.

272

273 **Acknowledgments**

274 The CHAMP mission is sponsored by the Space Agency of the German Aerospace Centre (DLR)
 275 through funds of the Federal Ministry of Economics and Technology, following a decision of the Ger-
 276 man Federal Parliament (grant code 50EE0944). Data retrieval and operation of the CHAMP satellite
 277 by the German Space Operations Centre (GSOC) is acknowledged. The Ørsted Project was made pos-
 278 sible by extensive support from the Danish Government, NASA, ESA, CNES, DARA and the Thomas
 279 B. Thriges Foundation while the SAC-C mission was supported by CONAE together with NASA and
 280 DMI / DTU Space. The institutes that support magnetic observatories together with INTERMAG-
 281 NET are thanked for promoting high standards of observatory practice. This is IPGP contribution no.
 282 XXXX. W.K., A.T. and Z.W. were funded by NASA and the NSF. The IGRF-11 task force also wishes
 283 to express their gratitude to C. Manoj for maintaining the IGRF web pages at NGDC.
