| REFERENCE Proudman Oceanographic Laboratory, Report No. 42, 49pp. + appendices | |
| ABSTRACT | <p>This report describes analysis of data obtained using the POL STABLE rig deployed off the Holderness coast during October, 1994 as part of the LOIS RACS(C)-I experiment. Data from electromagnetic current meters and a sensitive pressure sensor are utilised to examine local hydrodynamic conditions arising through interactions between tidal currents and waves. The average concentration of suspended particulate matter (SPM), measured using optical and acoustic devices are described and observed temporal variability in SPM time series is examined using concurrent hydrodynamic information. Recommendations for further research are stated. An electronic data base containing selected STABLE data accompanies this report.</p> |

12.0 Appendix 2 *Microsoft Excel* data base **STABLE.xls**

1.0 Introduction

The report describes the analysis of data from STABLE (Sediment Transport And Boundary Layer Equipment, Figure 1a, Humphery, 1987; Humphery & Moores, 1994), an autonomous instrument platform designed to measure near-bed fluid motions and suspended sediment concentrations with high temporal resolution. Deployed as part of the Holderness Experiment (*c.f. Prandle, 1994*) in the NERC LOIS RACS(C) Programme during October, 1994 and during January-February, 1995 STABLE has been utilised to obtain measurements of local sediment resuspension, transport and accretion processes. The work presented in this report is part of the data dissemination resulting from the Holderness experiment and examines in detail, data resulting from the first STABLE deployment in October, 1994. A follow-up POL report will examine data from the second STABLE deployment at Holderness.

1.1 Background

The Holderness coast, composed principally of glacial till, is rapidly retreating (*circa* 2 m/year) and represents the largest single source of sediments to the North Sea (*Prandle, 1994*). The morphology and associated sediment dynamics of the Holderness coastline are discussed by *Pethik & Leggett (1993)* who ascribe the bulk of sand size sediment transport to wave action. Waves with a return period in the range 8-15 months are thought to mobilise the majority of offshore sediments and contribute to the bulk of the observed net southerly drift of sediments along the coast. Waves with more frequent return periods and generally lower energy are not considered to contribute significantly to net sediment transport. Given that sediments originating from this source may play a major role in determining water quality in large areas of the North Sea, the Holderness experiment aimed to provide a comprehensive data set to improve understanding of physical processes and to enable the development, parameterisation and validation of dynamically and sedimentological numerical models.

The Holderness experiment was conducted during October 1994 to March, 1995, and brought together a wide range of observational expertise and hardware in an integrated and comprehensive field measurement campaign (*Figure 1b*). Waves were measured at inshore and offshore sites using wave buoys, bottom pressure recorders and X-Band radar in order to provide a framework for describing wave climate and the frequency of extreme events likely to have a significant impact upon sediment dynamics. The measurements also provided a large synoptic data set with which to study wave transformations in shallow water. Other instrumentation utilised during the experiment included POL acoustic Doppler current profilers (ADCP), acoustic backscatter devices (ABS), pressure recorders and InterOcean S4DW current meters deployed together as POL Mooring Packages (PMP's). In addition, the HF radar system OSCR, deployed to measure surface currents over a wide area, and ERS-1 SAR images provide remotely sensed data to aid understanding of physical processes at the Holderness field site. Analysis of wave data undertaken since the end of the field experiment is described by *Wolf (1996)*.

1.2 STABLE: Sediment Transport And Boundary Layer Equipment

The STABLE rig (*Figure 1a*) measured turbulence, surface waves and the concentration of suspended particulate matter in *burst* data acquisition mode at 8 Hz at heights (z) above the sea bed for 20 minutes every hour of rig deployment using electromagnetic current meters (ECM) at $z = 30.5$ cm and 60.3 cm, a sensitive pressure sensor at $z = 172.5$ cm and optical backscatter (OBS) instruments at $z = 30.5$ cm and 60.3 cm, respectively. In addition, the vertical concentration profile of suspended particulate matter (SPM) has been measured at 4 Hz in *burst* mode using a triple frequency acoustic backscatter system (ABS) at $z = 126.5$ cm. These data were logged independently and were synchronised precisely with *burst* ECM and pressure sensor data. Measurements of average current flow speed at four heights above the sea bed ($z = 39.0$ cm, 57.0 cm, 75.0 cm and 93.0 cm), average current direction ($z = 107.5$ cm), water depth ($z = 174.5$ cm) and rig orientation were recorded in *mean* mode at intervals of one minute. In addition, STABLE

acted as a platform to support sediment traps at $z = 184.5$ cm and 95.0 cm. Data from these instruments are not considered in the present report. A detailed description of the STABLE rig and data acquisition and storage and of the ABS system is given by *Humphery & Moores (1994)* and *Thorne et al., (1993)*.

1.3 Field site and STABLE deployment

STABLE was deployed from the *RV Corystes* on 14 October 1994 in approximately 25 m of water at a location off the Holderness coast ($53^{\circ} 49.448'N$, $00^{\circ} 06.936'E$, *Figure 1b*). In addition, the MAFF rigs *Tetrapod* and four *Minipods* were also deployed during the *Corystes* cruise in the vicinity of the STABLE site. Where possible data from these rigs will be integrated with data from the STABLE deployments in future studies.

Underwater television surveys showed the bottom sediments in the vicinity of the deployment site principally to be composed of gravel with fine sand between the interstices of the coarse grains. Relatively small areas of ephemeral sand sheets and ribbons with well developed ripples were also noted at sites inshore of STABLE. Such sediment assemblages are considered to be indicative of strong tidal current action at the sea bed which results in the development of a lag gravel bed armour deposit over sandy sediments. On the basis of evidence from other similar sites, such armour is likely only to be mobilise during extreme storm events. The resulting release of sandy sediments is likely to be large in such conditions.

Although the weather remained relatively calm during the experimental period, the STABLE rig mooring suffered some damage attributable to shipping activities and the electromagnetic current meters were found to be flooded on recovery owing to crevice corrosion. Despite these problems, STABLE acquired sufficient data to enable detailed investigations of local interactions between tidal currents, waves and sediments over a period of approximately 12.5 days. During the deployment, the offshore wave buoy at site

N4 (*Figure 1b*) recorded waves with a significant wave height (H_s) and period (T_z) exceeding 3.0 m and 11 s, respectively, around 19 October, 1994. However, H_s values in the range 1.0 - 1.5 m were more typical of the wave conditions during the majority of the deployment considered here.

2.0 Scope of report

This report describes preliminary analysis of STABLE and ABS data. Where possible, an assessment has been made of data quality and all spurious data values have been omitted. Fortunately, this has only been necessary in a small number of cases. In a few instances, missing or poor quality data values have been replaced with values derived using appropriate interpolation routines. Hydrodynamic parameters have been calculated to describe the average conditions pertaining at the STABLE deployment site during a given *burst* measurement period. These data have been fully calibrated and are presented in standard metric units. Whilst data relating to average suspended sediment concentrations are uncalibrated at the time of writing this report, they are relate linearly to actual concentrations and thus temporal variations in observed SPM values can be related directly to observed temporal variations in local hydrodynamic conditions.

Methodologies utilised to analyse STABLE data have been developed at POL (*Williams et al., 1996*) and follow methods described by *Soulsby et al. (1991)* and *Hannay et al. (1994)*. These methods have been validated using a 1DV random wave boundary layer model (*O'Connor et al., 1994*) for data obtained at a site off the Belgian coast in February, 1993 (*Williams et al., 1996*). *Section 4.0* outlines the approaches used to derive terms relating to the local, *burst* average hydrodynamic conditions and suspended sediment concentrations. Parameters derived from the STABLE data are then considered under the following categories: Tides; waves; turbulence; bed shear velocity; drag coefficient and apparent bed roughness; wave-current-bed interactions; and sediment dynamics. Use has been made of the software packages *Minitab 10.0* for statistical analysis and data plotting

and *Microsoft Excel* for data base management. The disk accompanying this report contains the STABLE data base used to produce all figures in this report in *Microsoft Excel* format.

3.0 Disclaimer and data ownership

All data and information contained in the data base accompanying this report have been compiled by the originating scientists. Whilst great care has been taken to ensure data validity, no promise, warranty or undertaking has been made or has been given by POL, for the use or interpretation of the data or by any accompanying information, software or materials. The recipient must rely on his/her own skill and judgement in further utilisation of this data base. All data remain the property of POL and users must acknowledge appropriate POL staff in any subsequent publications arising from use of the data contained in this report and accompanying data base.

4.0 Burst data analysis

The raw STABLE data set contained 499 *burst* data records of variable quality. The first 60 *bursts* were obtained prior to deployment of the STABLE rig and consequently were omitted from the analysis. ECM sensor malfunction towards the end of the deployment identified during preliminary analysis resulted in the rejection of additional *burst* data records. Abrupt termination of ECM data has been attributed to the corrosion problems noted above. Subsequent analyses have concentrated upon *bursts* 61 to 360 (approximately 12.5 days). During each *burst* data measurement period, 11 *burst* data channels (C) were logged at 8 Hz (9234 record per file) by the STABLE *burst* data logger. These included: uAp (C1); wAp (C2); uAs (C3); wAs (C4); uBp (C5); wBp (C6); uBs (C7); wBs (C8); OBS-1 (C9); OBS-2 (C10); and P (C11). Here: u and w refer to horizontal and vertical flow, respectively; A and B refer to ECM sensors at height above the sea bed (z) of 30.5 cm and 60.3 cm, respectively; p and s refer to port and starboard sensors, respectively; OBS-1 and OBS-2 refer to optical backscatter sensors at $z = 30.5$ cm and 60.3 cm, respectively; and P refers to the *burst* measurement of absolute pressure at $z = 172.5$ cm. ABS data from 4.0

MHz, 2.0 MHz and 700 KHz devices were recorded using an independent ABS data logger mounted on the STABLE rig with each ABS *burst* data acquisition period being synchronised precisely with a STABLE *burst*. Profiles of SPM obtained using the ABS system extended to $z = 126.5$ cm with a vertical resolution of 2 cm.

4.1 *Burst* ECM data

All *burst* ECM data channels were screened to check for and to remove spurious data values. Before proceeding with data analysis, *burst* average and standard deviation values for each data channel were calculated and plotted as time series to aid identification of sensor and/or logger malfunction. These data are shown in *Figure 2* and *Figure 3* where, for convenience, *burst* 0 on the x axis is equivalent to *burst* 61 of the STABLE deployment. This convention is used in all subsequent time series plots of *burst* average STABLE data. Horizontal and vertical ECM data channels (*Figure 2*) show clearly modulation at the tidal frequency and exhibit zero drift through time and varying degrees of zero offset error. The wAp channel (*Figure 2b*) was found to exhibit the greatest degree of sensor zero drift during *bursts* 61-360. Data analysis routines designed to ameliorate these errors are described below. Standard deviation values for all ECM data channels (*Figure 3*) also show tidal modulation and are shown to attain maximum values around *bursts* 100-150. It will be shown below that this results from the observed increase in surface wave height.

Regression techniques and a 9 point tidal filter were used successfully to remove sensor zero drift from the ECM time series (not found to exceed 10 cm/s in any case). Zero offset errors were removed by centring all ECM time series around zero using statistical methods. It was also necessary to correct for misalignment of the ECM sensors relative to the principal tidal flow streamline. The gradient of the regression line derived from plots of the *burst* average vertical flow component versus the *burst* average horizontal flow component (port and starboard, sensors A and B) was used to determine sensor misalignment angles relative to the principal streamline (θ). Sensor misalignment

corrections are applied to the zero-mean, detrended ECM time series using the formulations given in *Table 1*.

| Flow component | ECM rotation correction |
|----------------|---|
| wAp | wAp(cos(θ_1)) - uAp(sin(θ_1)) |
| uAp | wAp(sin(θ_1)) + uAp(cos(θ_1)) |
| wAs | wAs(cos(θ_2)) - uAs(sin(θ_2)) |
| uAs | wAs(sin(θ_2)) + uAs(cos(θ_2)) |
| wBp | wBp(cos(θ_3)) - uBp(sin(θ_3)) |
| uBp | wBp(sin(θ_3)) + uBp(cos(θ_3)) |
| wBs | wBs(cos(θ_4)) - uBs(sin(θ_4)) |
| uBs | wBs(sin(θ_4)) + uBs(cos(θ_4)) |

Table 1 Rotation of ECM channels

Values for θ_1 , θ_2 , θ_3 and θ_4 were found to be -0.91° , 0.80° , 3.75° and 0.86° , respectively, indicating strongly that STABLE rested upon a level surface during the deployment. The relatively large value for θ_2 is attributable primarily to inaccuracy in the manufacture of the ECM mounting spar and was noted by *Williams et al.*, (1996). Data from adjacent ECM heads were combined to obtain estimates of the flow components U, V and W within the measurement volume of the ECM pairs at $z = 30.5$ cm and 60.3 cm. The zero-mean flow components u' , v' and w' describing both turbulent and wave induced fluid motions were then calculated.

In order to obtain estimates of wave induced near-bed currents and near-bed turbulence intensity from ECM data it is necessary to isolate wave motions from the turbulent tidal flow components. This has been achieved through use of a spectral splitting technique described by *Soulsby & Humphery* (1989) to obtain separately the variance due to waves ($\overline{u'_w^2}$ and $\overline{v'_w^2}$) and turbulence ($\overline{u'_t^2}$ and $\overline{v'_t^2}$). The frequency bounds of the characteristic wave peak in u' and v' spectra for a given *burst* record were defined using the

bottom pressure spectrum. The method is used to obtain separate wave and turbulent variance for each horizontal flow component from which *burst* average RMS wave orbital velocity (σ_w) and *burst* average wave direction ($\bar{\Psi}_w$) are obtained using

$$\sigma_w = (\overline{u'_w}^2 + \overline{v'_w}^2)^{1/2} \quad (1)$$

$$\bar{\Psi}_w = \tan^{-1} (\overline{v'_w} / \overline{u'_w}) \quad (2)$$

Variance due to turbulence (i.e. $\overline{u'^2}$, $\overline{v'^2}$ and $\overline{w'^2}$) in the time series u' , v' and w' were utilised subsequently to obtain estimates of bed shear velocity (see *Section 7.4*).

Williams et al., (1996) found it advantageous to determine the optimum temporal position in the vertical flow time series in subsequent eddy correlation analyses. Cross-correlation analysis was first used to determine the lag between port and starboard w time series at a given height and thereby allow temporal ‘centring’ of the w series within the ECM measurement volume. Since a strong correlation is found to exist between the lag and the average current speed it is possible to automate this correction in subsequent analyses using a regression technique. Lags up to 2 seconds were observed at low flow velocities.

4.2 *Burst* pressure data

The *burst* pressure channel P was found to be corrupted by noise spikes (exceeding > 2 standard deviations for a given time series) and by a data logging problem that caused the *burst* pressure records to suddenly jump between two DC offset levels when the values in the pressure time series exceeded a certain value. Both these problems were corrected automatically using software. Selected *burst* pressure records were corrected for depth attenuation using linear theory. Good agreement was found between observed significant wave height (H_s) and significant wave period (T_z) values derived from STABLE data and

values from wave buoys in the vicinity of the STABLE deployment site (*Figure 1b*). In the present work, *burst* pressure data have been used to define the band width of gravity wave frequencies for use in a spectral method to obtain estimates of wave orbital speeds near the sea bed (see *Section 4.1*).

4.3 *Burst* OBS data

Burst average output from the two OBS sensors initially was examined visually. Whilst OBS-1 values ($z = 30.5$ cm) were found to change sporadically by more than 2 standard deviations, OBS-2 values ($z = 60.3$ cm) were subject to much less inter-*burst* variability and correlated visually with observed hydrodynamic changes. It was necessary to edit the OBS-1 time series to remove all spurious data values utilising linear interpolation between adjacent good data points. There is thus a degree of uncertainty associated with this time series and its use in future studies must therefore be treated with caution. Whilst present OBS data express the relative concentration of suspended sediment, calibration of the sensors is required in order to determine actual concentration values.

4.4 *Burst* ABS data

Following removal of spurious data spikes and application of a calibration routine, burst average values were calculated for ABS data obtained from devices operating at 4.0 MHz, 2.0 MHz and 700 KHz for each of the 64 measurement cells. The calibration routine converted ABS voltages to decibels using an appropriate polynomial expression for a given ABS sensor. These data were subsequently converted into values which relate directly to sediment concentration. The STABLE data base accompanying this report contains selected ABS data from measurement cells 9, 19, 29, 39, 49 and 59 for each ABS measurement frequency. At the time of writing this report, work to give an absolute calibration for the instruments is currently underway.

5.0 Mean data analysis

Laboratory determine calibrations were applied to rotor, vane, pitch, roll, compass and pressure data and the resulting time series plotted for visual inspection. In all cases data were found to be free from noise spikes and spanned the entire period of the *burst* data. However, the rig pitch and roll sensors malfunctioned and no useful data was obtained. In general, the measured tidal current speed was observed to increase with height above the sea bed and current direction indicated by the vane conferred in phase with data from adjacent moorings. However, closer inspection of the rotor data showed current speed estimates to be highly variable with few observed velocity profiles correlating with $\log(z)$ (i.e. R^2 values less than 0.60). Based upon experience of these data from other STABLE deployments it is speculated that rotors malfunctioned during the present deployment, probable due to fouling. Further consideration of these data is given below.

6.0 Data base description

To facilitate easier access to the information contained in this report, a data base containing all hydrodynamic parameters and sediment concentration information derived from the present STABLE data set is include on the floppy disk which accompanies this report. Both *burst* average and *mean* data sets are included. Attention is drawn to *Section 2.0* of this report regarding data integrity and intellectual property rights.

The data base is held in the *Microsoft Excel* file **STABLE.xls**, *Appendix 2*. *Burst* average hydrodynamic parameters and sediment concentration values in this data base are defined in *Appendix 1* which lists the column numbers, column headers and includes a description and definition of the various terms derived from the raw *burst* ECM, pressure, OBS and ABS data channels and mean data channels described above.

7.0 Data description

This section describes selected ***burst average*** STABLE data which illustrate clearly the hydrodynamic conditions pertaining at the present field site during the experimental period 15 - 27 October 1994. All data plots have been produced utilising the data in **STABLE.xls** using the graphics facilities in the *Minitab V10.0* package. In most cases, owing to close similarity between data sets obtained at $z = 30.5$ cm and $z = 60.3$ cm, only data from one specified measurement height is presented in order to maintain data presentation clarity.

7.1 Tides

Tidal variations in water depth approximately in the range 21 m to 26 m are illustrated in *Figure 4*. These data show part of a neap-spring-neap tidal cycle with little additional surge component consistent with the relatively calm weather during most of the experiment. Variations in tidal current speed at $z = 30.5$ cm approximately in the range 5 - 55 cm/s are shown in *Figure 5*. Also shown is the tidally average current speed demonstrating modulation consistent with a neap-spring-neap cycle. The plot of *burst average* U and V flow components in *Figure 6* show the tidal ellipse to be relatively narrow and indicative of approximately rectilinear tidal motion. Tidal current and Reynolds stress directions are illustrated in *Figure 7*. As expected there is a strong visual correlation between these two time series indicating that bed shear stress is aligned approximately with the tidal currents. Surface wave activity has no detectable influence upon *burst average* Reynolds stress direction values. Bedload sediment transport would be expected therefore, to follow closely the average tidal current direction during the present measurement period.

Burst average rotor data are shown in *Figure 8*. Offsets are applied artificially to these data to permit inter-comparison between the different measurement heights. The scatter plot in *Figure 9* shows the relationships between tidal current speed measured by the rotors and by the ECM sensors at $z = 60.3$ cm. In general, the agreement is good.

7.2 Waves

Time series of *Burst* average RMS wave orbital speed (σ_w) measured at $z = 30.5$ cm is shown in *Figure 10*. Owing to the relatively low wave activity (maximum $H_s \approx 3.0$ m during 19 October, 1994), maximum σ_w speeds do not exceed 10 cm/s and in most cases are less than 5 cm/s. σ_w values obtained theoretically from surface wave elevation data using linear theory agree well with σ_w values obtained from STABLE data. *Figure 10* show also the modulation in σ_w resulting from changes in water depth during the tidal cycle. Close similarity between σ_w values at $z = 30.5$ cm and $z = 60.3$ cm is shown in *Figure 11*. Slightly higher speeds measured at $z = 60.3$ cm is consistent with other STABLE data (*c.f. Williams et al., 1995*) and is attributable to wave-current interaction. Such close similarity between σ_w values at each measurement height indicates strongly that the spectral splitting method used to obtain these data gives results consistent with theory.

7.3 Turbulence

Following removal of variance attributable to surface waves using the spectral splitting method described above, RMS turbulence intensity values were calculated for the zero-mean turbulent flow components u' , v' and w' at $z = 30.5$ cm and 60.3 cm. Here RMS values are defined as $(\overline{u'^2})^{0.5}$, $(\overline{v'^2})^{0.5}$ and $(\overline{w'^2})^{0.5}$ where the subscript t denotes turbulent fluctuations in the absence of waves. RMS normalised turbulence intensity values for u' , v' and w' time series are illustrated as time series in *Figure 12*. Average values for the whole deployment are shown in *Table 2*.

| z | Normalised RMS turbulence intensity | | |
|---------|-------------------------------------|-----------------------------|-----------------------------|
| | $(\overline{u'})^{0.5}/U_*$ | $(\overline{v'})^{0.5}/U_*$ | $(\overline{w'})^{0.5}/U_*$ |
| 60.3 cm | 3.16 | 3.32 | 1.02 |
| 30.5 cm | 3.16 | 4.05 | 1.06 |

Table 2 Normalised RMS turbulence intensity values

Data in *Table 2* is consistent with measurements obtained in other geophysical boundary layers widely reported elsewhere (*c.f.* Soulsby, 1983). *Figure 12* shows that irrespective of the flow component considered the scatter of data values increases as the tidal current speed decreases. Further data analysis outside the scope of the present study is required to explain these observations and will be the subject of future publications.

Power spectra (E) over a frequency range $f = 0.0025 - 4.0$ Hz were obtained from u' , v' and w' time series obtained at $z = 30.5$ cm and 60.3 cm using a fast Fourier transform (FFT). An approximately $f^{-5/3}$ power law behaviour consistent with theory was observed for frequencies greater than 1.0 Hz for all *bursts*, and an approximately f^{-5} power law decay was evident for wave frequencies in the range $0.1 - 0.3$ Hz during *bursts* when waves were present. This result indicates that turbulence generated at the sea bed by wave action, with frequencies greater than approximately 0.5 Hz, cannot be detected by the present ECM sensors at $z \geq 30.5$ cm. All spectra derived from the flow components u' , v' and w' at $z = 60.5$ cm (i.e. *bursts* 61 to 360) are illustrated as 2D contour plots in *Figure 14(a)*, *Figure 14(b)* and *Figure 14(c)*, respectively. These *figures* show clearly modulation of spectral energy due to tidal forcing across all frequencies. In addition, *Figure 14(a)* and *14(b)* show evolution and decline of a characteristic peak in spectral energy at approximately 0.125 Hz attributable to surface waves (period ≈ 8 seconds) during the storm. The principal characteristics of turbulence spectra for u' , v' and w' components at $z = 30.5$ cm were found to be essentially the same as those obtained at $z = 60.3$ cm.

Figure 14(c) shows little evidence of wave activity during the experiment. However, there is perhaps a small peak in energy at approximately the wave frequency during *bursts* 150 to 300, indicating a leakage of wave orbital motion into the vertical channel. It is considered that this occurs due to momentary misalignment of the ECM sensor relative to the principal streamline, (*c.f.* Williams *et al.*, 1996). Such sensor misalignment may have

implications when utilising Reynolds stress estimates to determine bed shear stress and is given consideration by *Williams et al., (1996)*.

Co-spectra for u' and v' components (not illustrated) showed significant scatter in spectral estimates across all frequencies. In terms of the spectral wavelength λ_s at height z above the sea bed (*Soulsby, 1983*), where $\lambda_s = \hat{S}_z / f$, approximately 80% of the covariance is associated with λ_s values in the range $1.0 < \lambda_s < 350$ m for *bursts* 61-360. This range of λ_s values is observed to decrease progressively in response to increasing wave height.

Whilst the time-average of u' , v' and w' is zero, the time average of their squares and mixed products are not and thus a net force or *Reynolds stress* arises in all turbulent flows. Owing to the conservation of momentum, a parcel of low momentum fluid moving away from a boundary to a region of higher velocity flow in a typical turbulent boundary layer would accelerate the fluid were it not for friction (i.e. $-\rho u' w'$, or *shear stress*). Since the fluctuating velocities in any two orthogonal planes are inversely correlated, a positive u' is associated with a negative w' (and *vice versa*), and thus the shear stress resulting from turbulent motions is positive. Similar arguments hold for all possible combinations of u' , v' and w' . The total time averaged stress at any point in a shear flow is described by the Reynolds stress tensor (∇) where

$$\nabla = -\rho \begin{bmatrix} U^2 & UW & VW \\ V^2 & UV & \\ W^2 & & \end{bmatrix} + -\rho \begin{bmatrix} u'^2 & u'w' & v'w' \\ v'^2 & & u'v' \\ w'^2 & & \end{bmatrix} \quad (3)$$

Terms in the left and right hand matrix include all turbulent and wave motions and represent the *burst* average and fluctuating stress terms, respectively. In the present report, the *burst* average Reynolds stress terms u'^2 , v'^2 , w'^2 , $\overline{u'w'}$, $\overline{v'w'}$ and $\overline{u'v'}$ have been calculated to facilitate investigation of the interactions between surface waves and tidal

currents. Instantaneous stress terms, involving the cross-product of the *burst* average stress and fluctuating stress terms are not considered here.

Temporal variation in the Reynolds stresses $\overline{u'w'}$, $\overline{v'w'}$ and $\overline{u'v'}$ measured at $z = 30.5$ cm is shown in *Figure 13*. Owing to the orientation of STABLE relative to the principal flow direction $\overline{v'w'}$ values are larger than $\overline{u'w'}$. Statistical description of all *burst* average Reynolds stress time series at $z = 30.5$ cm and 60.3 cm is given in *Table 3* and *Table 4*. Good agreement between ECM measurement heights is clearly evident.

| Variable | N | Mean | Median | St.Dev. | Min. | Max. | Q1 | Q3 |
|-------------------|-----|-------|--------|---------|--------|--------|-------|-------|
| $\overline{u'w'}$ | 300 | -0.09 | 0.25 | 2.06 | -9.86 | 4.17 | -1.06 | 1.17 |
| $\overline{v'w'}$ | 300 | 0.34 | 0.11 | 2.64 | -4.84 | 8.10 | -1.39 | 1.76 |
| $\overline{u'v'}$ | 300 | 12.80 | 3.11 | 26.91 | -20.29 | 175.50 | -3.79 | 19.94 |

Table 3 Reynolds stress descriptive Statistics, $z = 30.5$ cm

| Variable | N | Mean | Median | St.Dev. | Min. | Max. | Q1 | Q3 |
|-------------------|-----|-------|--------|---------|--------|--------|-------|-------|
| $\overline{u'w'}$ | 300 | -0.11 | 0.08 | 2.64 | -10.86 | 7.14 | -1.14 | 1.44 |
| $\overline{v'w'}$ | 300 | 0.74 | 0.21 | 3.03 | -5.44 | 9.76 | -1.37 | 2.68 |
| $\overline{u'v'}$ | 300 | 12.23 | 2.99 | 25.12 | -21.84 | 164.17 | -2.83 | 18.91 |

Table 4 Reynolds stress descriptive Statistics, $z = 60.3$ cm

Large values of the lateral Reynolds stress $\overline{u'v'}$ indicative of strong current shear in the near-bed region shown in *Figure 13* spanning *bursts* 100 - 180. *Figure 15*, showing the relationship between $\overline{u'v'}$ and RMS wave orbital speed, suggests that large $\overline{u'v'}$ values may be attributable in part to wave-current interactions ($R^2 = 0.54$). Similar large lateral

Reynolds stress values are reported by *Williams et al. (1996)* during storm conditions at a site close to a large offshore sand bank.

7.4 Bed shear velocity

Estimation of average bed shear velocity (\bar{U}^*) is widely recognised as being subject to errors which arise from a number of sources. In the present study four methods have been used to estimate *burst* average bed shear velocity (\bar{U}^*) using STABLE data: Logarithmic profile (LP); Reynolds stresses (RS); turbulent kinetic energy (TKE) and; the inertial dissipation methods (ID). Assumption of a logarithmic distribution of average velocity with height is found to be valid in studies of wave plus current condition reported by *Kemp & Simons (1983)*. In the LP method reported here, estimates of \bar{U}^* are obtained using a least squares regression fit to selected ECM (LP_{ECM}) and rotor (LP_R) data, (*Soulsby et al., 1991 and; Bergeron & Abrahams, 1992*). *Burst* ECM and rotor data obtained during periods of rapid flow acceleration/deceleration or when $\hat{S}_{40} < 20$ cm/s were rejected. In such circumstances, turbulence level and stress is likely to be enhanced and constant stress layer assumptions are invalidated. All velocity profiles were averaged over a period corresponding precisely with a given *burst*. As noted above, few velocity profiles measured by the rotors conformed to a logarithmic velocity distribution with height above the sea bed resulting in a paucity of \bar{U}^* estimates derived from this method.

Assuming a constant stress layer up to 0.1d (i.e. ≈ 2 m), shear velocity has also been estimated using *burst* ECM data at $z = 30.5$ cm and $z = 60.3$ cm using the Reynolds stress (RS, *Equation 4*) and turbulent kinetic energy (TKE, *Equation 5*) methods.

$$\bar{U}_{RS}^2 = (\tau/\rho) = \{(\overline{-u'_t w'_t})^2 + (\overline{-v'_t w'_t})^2\}^{1/2} \quad (4)$$

$$\bar{U}_{TKE}^2 = (\tau/\rho) = 0.19 (E_T) \quad (5)$$

where $\overline{-u'_t w'_t}$ and $\overline{-v'_t w'_t}$ are *burst* average Reynolds stress values excluding waves, $E_T = 0.5(\overline{u'^2}_t + \overline{v'^2}_t + \overline{w'^2}_t)$ and the constant of proportionality (0.19) is given by *Soulsby (1983)*.

As an additional check of \overline{U}^* estimates described above, use was made of the inertial dissipation (ID) method (*Xu et al., 1994*) to determine sea bed stress. Here

$$U^* = \left[\phi_{ii}(k) k^{*3} / \alpha_i \right]^{1/3} (kz)^{1/3} \quad (6)$$

where $\phi_{ii}(k)$ is the i^{th} turbulent velocity component of the wavenumber (k) spectrum, α_i is the appropriate Kolmogorov constant (0.54, *Williams & Paulson, 1977*) and k^* is von Kármáns constant (0.4). Estimates of \overline{U}^* at low Reynolds numbers ($Re < 3000$, where $Re = \overline{U}^* kz_{cr} / v$ and z_{cr} is the critical height above the bed and v is kinematic viscosity) were adjusted using the method described by *Huntley (1988)*. As expected \overline{U}^* values obtained using the ID method were found to be very similar to the \overline{U}^* values from the TKE method and are consequently not presented here.

Results from these analyses are presented in *Figure 16* which shows tidal modulation of \overline{U}^* at $z = 30.5$ cm and the neap-spring-neap cycle identified above. In general, there is reasonable agreement between the RS and TKE estimates of \overline{U}^* . In contrast, estimates of \overline{U}^* obtained from ECM and rotor data using the LP method exhibit a large scatter with values of \overline{U}^* only approximately coincident with the RS and TKE estimates during certain phases of the tide. This is consistent with results obtained from other STABLE data sets (e.g. Norfolk sand banks; and CSTAB) and results from the combined effect of flow acceleration and possibly minor stratification effects which tend to invalidate assumptions regarding the vertical velocity structure in the boundary layer. Similar effects are noted below when considering apparent bed roughness and drag and will be the subject of future investigations by the authors. Close similarity between \overline{U}^* estimates obtained using the TKE method at $z = 30.5$ cm and $z = 60.3$ cm is shown in *Figure 17*. Slightly larger \overline{U}^*

values at $z = 30.5$ cm are attributable to: the proximity of the wave boundary layer; and ECM sensor turbulence resolution (*c.f.* Williams *et al.*, 1995). \bar{U}^* data are found to conform approximately to the quadratic friction law.

7.5 Drag coefficient and apparent bed roughness

The drag coefficient (C_d) is related to stress magnitude (τ/ρ) estimates at $z = 30.5$ cm and 60.3 cm (TKE method) by $C_d = (\tau/\rho)/\hat{S}_z^2$ and apparent bed roughness (z_a) is related to drag coefficient values at height z (C_z) by $z_a = z e^{(-k/C_z^{0.5})}$. Burst average values of C_d and z_a are included in the data base. Estimated values of the drag coefficient (C_d) at $z = 30.5$ cm derived using RS and TKE estimates of \bar{U}^* are shown in *Figure 18*. In common with estimated \bar{U}^* values presented above, C_d values are apparently subject to modulation at the tidal frequency. *Table 5* gives a statistical description of the C_d (TKE) time series obtained at $z = 30.5$ cm and $z = 60.3$ cm.

| Variable | z (cm) | N | Mean | Median | StDev | Min. | Max. | Q1 | Q3 |
|-------------|----------|-----|--------|--------|-------|---------|--------|--------|-------|
| C_d (TKE) | 30.5 | 294 | 0.0019 | 0.0011 | 0.024 | 0.00045 | 0.0216 | 0.0008 | 0.002 |
| C_d (TKE) | 60.3 | 294 | 0.0019 | 0.0011 | 0.020 | 0.00048 | 0.0153 | 0.0008 | 0.002 |

Table 5 Statistical description of C_d (TKE) burst average data values

Irrespective of the measurement height, the mean C_d value of 0.0019 is a little lower than values normally chosen to characterise bottom drag in existing numerical models (i.e. 0.0025). Apparent bed roughness implied by these results is relatively low and consistent with typical values for sea bed morphology at the present study site.

The relationship between C_d (TKE) and *burst* average tidal current speed shown in *Figure 19* demonstrates the scatter of data values and apparent enhancement of C_d values at current speeds less than approximately 20 cm/s. In common with findings presented above,

changes to the boundary layer resulting in distortion of the log-law region is identified as the principal source of data scatter. Without further investigation of this phenomenon it is not possible to use these data in related studies.

It is considered that the present time series of estimated drag coefficient values is of high quality and reflects genuine physical changes in local hydrodynamic conditions during the experimental period. As such, this data is very useful in assessing the validity of certain data analysis procedures and will be the subject of further work by the authors.

7.6 Wave-current-bed interactions

Figure 20, showing the relationship between RMS wave orbital speed/current speed (σ_w/S) and TKE/current speed² (TKE/S^2) indicates a progressive increase in the production of turbulent kinetic energy in response to an increase in the wave:current ratio. Since the value of TKE/S^2 should be approximately constant for a given bed roughness (Soulsby & Humphrey, 1989), *Figure 20* suggests that either the physical roughness of the sea bed changes during the experiment or that the additional turbulence generated at the sea bed through the action of wave motion can be detected by the ECM sensors. Similar interpretations are applicable also to data presented in *Figure 21* which shows the relationship between σ_w/S and Cd. However, as a note of caution it should be noted that in common with large TKE/S^2 in *Figure 20*, the large Cd values in *Figure 21* are generally occur close to slack water when tidal acceleration effects are likely to invalidate assumptions made regarding the vertical structure of the near-bed boundary layer. It is recommended that these results should be examined closely in future investigations.

7.7 Sediment dynamics

In addition to the preliminary investigation of hydrodynamic parameters derived from the STABLE *burst* data set, the present investigation also examined data from the optical backscatter sensors at $z = 30.5$ cm (OBS-1) and $z = 60.3$ cm (OBS-2) and from a triple

frequency acoustic backscatter device (ABS) operating at 4.0 MHz, 2.0 MHz and 700 KHz. At the time of writing this report, calibration of these instruments has not been completed so comments here are restricted to a description of observed relationships between uncalibrated SPM data and various hydrodynamic variables considered to be important in sediment entrainment, resuspension, transport and accretion processes.

7.7.1 OBS data

The temporal relationship between current speed, current direction and OBS data is shown in *Figure 22*. Maximum OBS data values are observed to be approximately coincident with the period of maximum tidal currents (*Figure 5*) and with the period of maximum RMS wave orbital speed (*Figure 10*). Modulation of the OBS data appeared to be slightly out phase with maximum current speeds and to some degree exhibited the ‘double peak’ characteristics associated with local resuspension and tidal advection maxima over the period of the semi-diurnal tide (*Weeks & Simpson, 1991*). Some evidence for a net ‘southerly’ drift of SPM is indicated by the OBS sensors which show SPM ‘concentration’ to be larger for mean tidal flow directions (Ψ_c) $\approx 100^\circ$ than for $\Psi_c \approx 300^\circ$. Correlation between *burst* average current speed and OBS data was not found to be statistically significant ($R^2 = 0.02$). However, statistically significant correlation ($R^2 = 0.527$), observed between RMS wave orbital speed and OBS data (*Figures 23 and 24*), indicates strongly that weak wave activity during the present experimental period resulted in local resuspension of sediments. Residuals from the regression of OBS data on RMS wave orbital speed were not found to correlate with any hydrodynamic parameters derived in the present study. In common with observed SPM reported by *Williams et al., (1996)*, links between observed SPM and hydrodynamic conditions measured at a given locality remain unclear probably owing to the advection of fine particles through the study area that may or may not originate from the immediate area or from local hydrodynamic forcing.

7.7.2 ABS data

Time series from selected ABS measurements cell are shown in *Figure 25* (a)-(c) for the 700 KHz 2.0 MHz and 4.0 MHz devices, respectively. At the present stage of the investigation it is not possible to ascribe an absolute concentration of SPM to any of these measurements. Irrespective of the device measurement frequency, *Figure 25* shows that SPM concentrations are modulated strongly by variation in tidal current speed and decline with distance above the sea bed. Further, maximum observed SPM concentrations are coincident with the period of maximum RMS wave orbital speed (*Figure 10*). These results indicate strongly the important role of waves in local sediment resuspension dynamics. Selected typical *burst* average SPM concentration profiles are shown in *Figure 26*. Each curve exhibits the classic exponential form observed at many other locations in numerous studies of suspended sediment dynamics dominated by tidal flows. It is not possible to comment further upon data quality or to speculate upon the likely sediment dynamics at the present study site without there being further work on the ABS data. This will be undertaken at POL during 1996/97.

A comparison between relative SPM concentration time series recorded by the OBS and ABS devices is shown in *Figure 27*. The general trend in these data showing a maximum around burst 120 is similar in both cases and peaks in SPM concentration at approximately the tidal frequency are observed to be approximately coincident. Cross-correlation coefficients obtained from the OBS and ABS series are summarised in *Table 6*. These data show a statistically significant correlation between OBS and ABS time series.

| ABS cell | R^2 (OBS-1) | R^2 (OBS-2) |
|-------------|------------------|------------------|
| 6 | 0.772 | 0.716 |
| 8 | 0.773 | 0.715 |
| 10 | 0.768 | 0.713 |
| 12 | 0.762 | 0.711 |
| 14 | 0.756 | 0.709 |
| 16 | 0.755 | 0.711 |
| 18 | 0.752 | 0.713 |
| 20 | 0.757 | 0.719 |

Table 6 Cross-correlation coefficient (R^2) between ABS backscatter pressure (4.0 MHz) at measurement cells 6, 8, 10, 12, 14, 16, 18, and 20 and OBS signals at $z = 30.5$ cm and 60.3 cm.

8.0 Summary and acknowledgements

- ◆ The broad aims of the Holderness experiment are outlined briefly and the experimental site and instrumentation is described. High quality STABLE data have been obtained which describe local hydrodynamic conditions and suspended sediment dynamics.
- ◆ A brief description of the STABLE rig is given to familiarise the reader with sensors and data logging facilities.
- ◆ Selected data from the first STABLE deployment in the Holderness experiment during October, 1994 are presented and described. These data are considered to have value in a number of POL projects.
- ◆ *Burst average* STABLE data are examined under the following headings:
 - ◊ tides;
 - ◊ waves;
 - ◊ turbulence;
 - ◊ bed shear velocity;
 - ◊ drag coefficient and apparent bed roughness;
 - ◊ wave-current-bed interactions; and

- ◊ sediment dynamics.
- Selected data are presented as time series plots, scatter plots and power spectra. Initial comments are made regarding data quality and integrity. Data worthy of further investigation are identified and suggestions for further research are stated.
- Attention is drawn to links between observed hydrodynamic parameters and observed SPM. Use of these data in future studies and numerical modelling of local sediment mobilisation and transport is strongly advocated.
- A data base in *Microsoft Excel* format is included with this report on a 3.5" floppy diskette. All figures included in this report were prepared from these data.

Thanks are extended to Peter Thorne, Peter Hardcastle, and Paul Bell at POL. This study forms part of the Holderness Experiment (LOIS RACS(C)) and results also contribute to the CAMELOT Project funded by the Flood and Coastal Defence Division of MAFF.

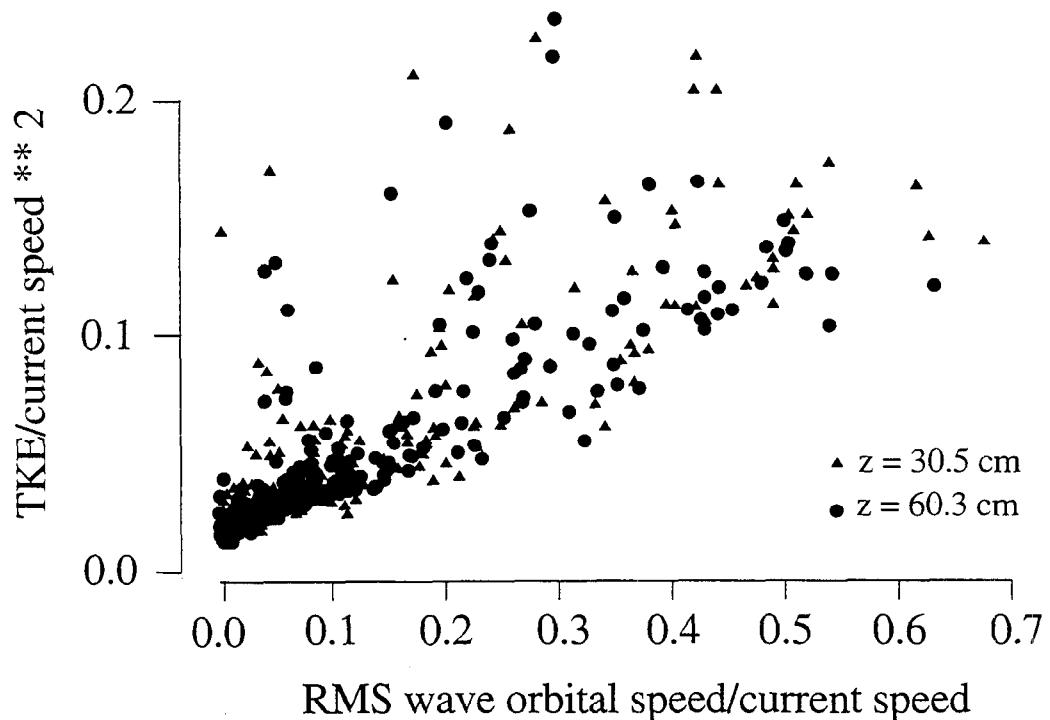

Figure 20 Scatter plot of *burst* average $(TKE/\text{current speed})^2$ versus the wave:current ratio at $z = 30.5$ cm and 60.3 cm.

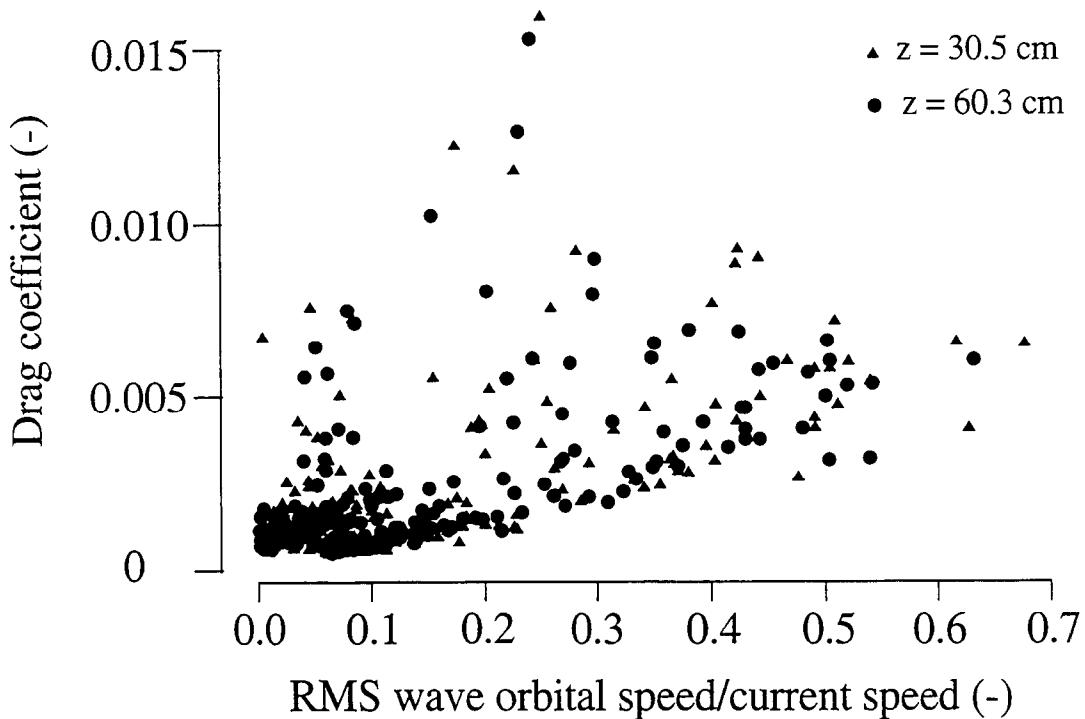

Figure 21 Scatter plot of *burst* average drag coefficient (derived from TKE estimates of \bar{U}^*) versus the wave:current ratio at $z = 30.5 \text{ cm}$ and 60.3 cm .

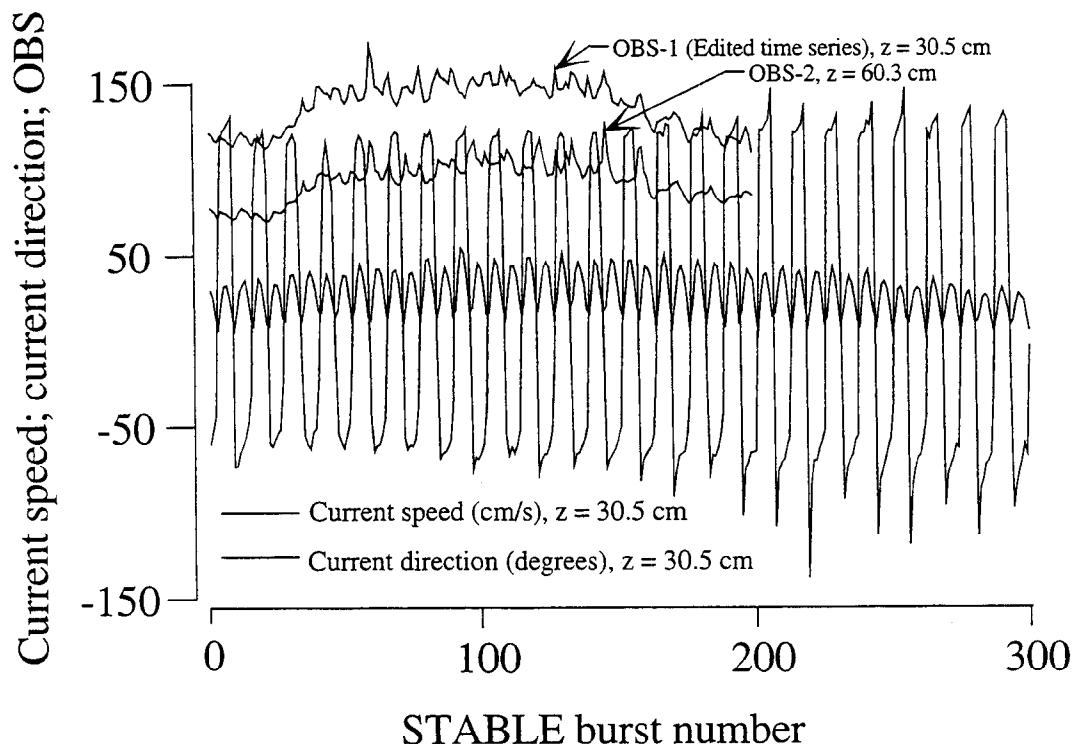

Figure 22 Time series plots of *burst* average tidal current speed and direction ($z = 30.5 \text{ cm}$), and OBS time series at $z = 30.5 \text{ cm}$ and 60.3 cm .

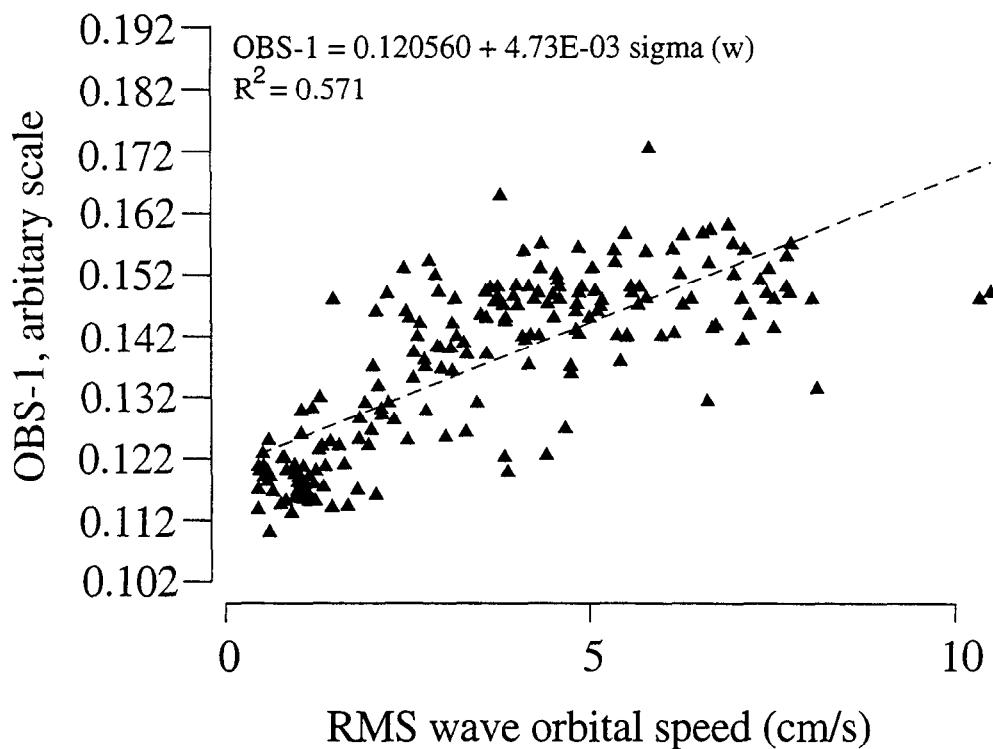

Figure 23 Scatter plot of *burst* average RMS wave orbital speed versus *burst* average OBS suspended sediment measurements at $z = 30.5$ cm.

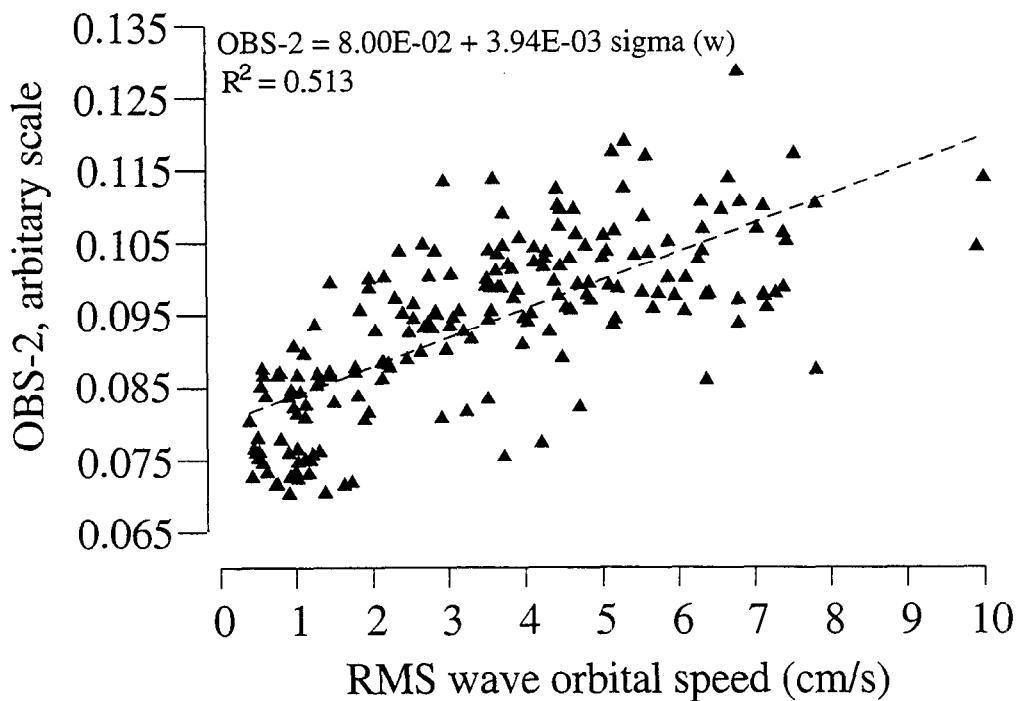

Figure 24 Scatter plot of *burst* average RMS wave orbital speed versus *burst* average OBS suspended sediment measurements at $z = 60.3$ cm.

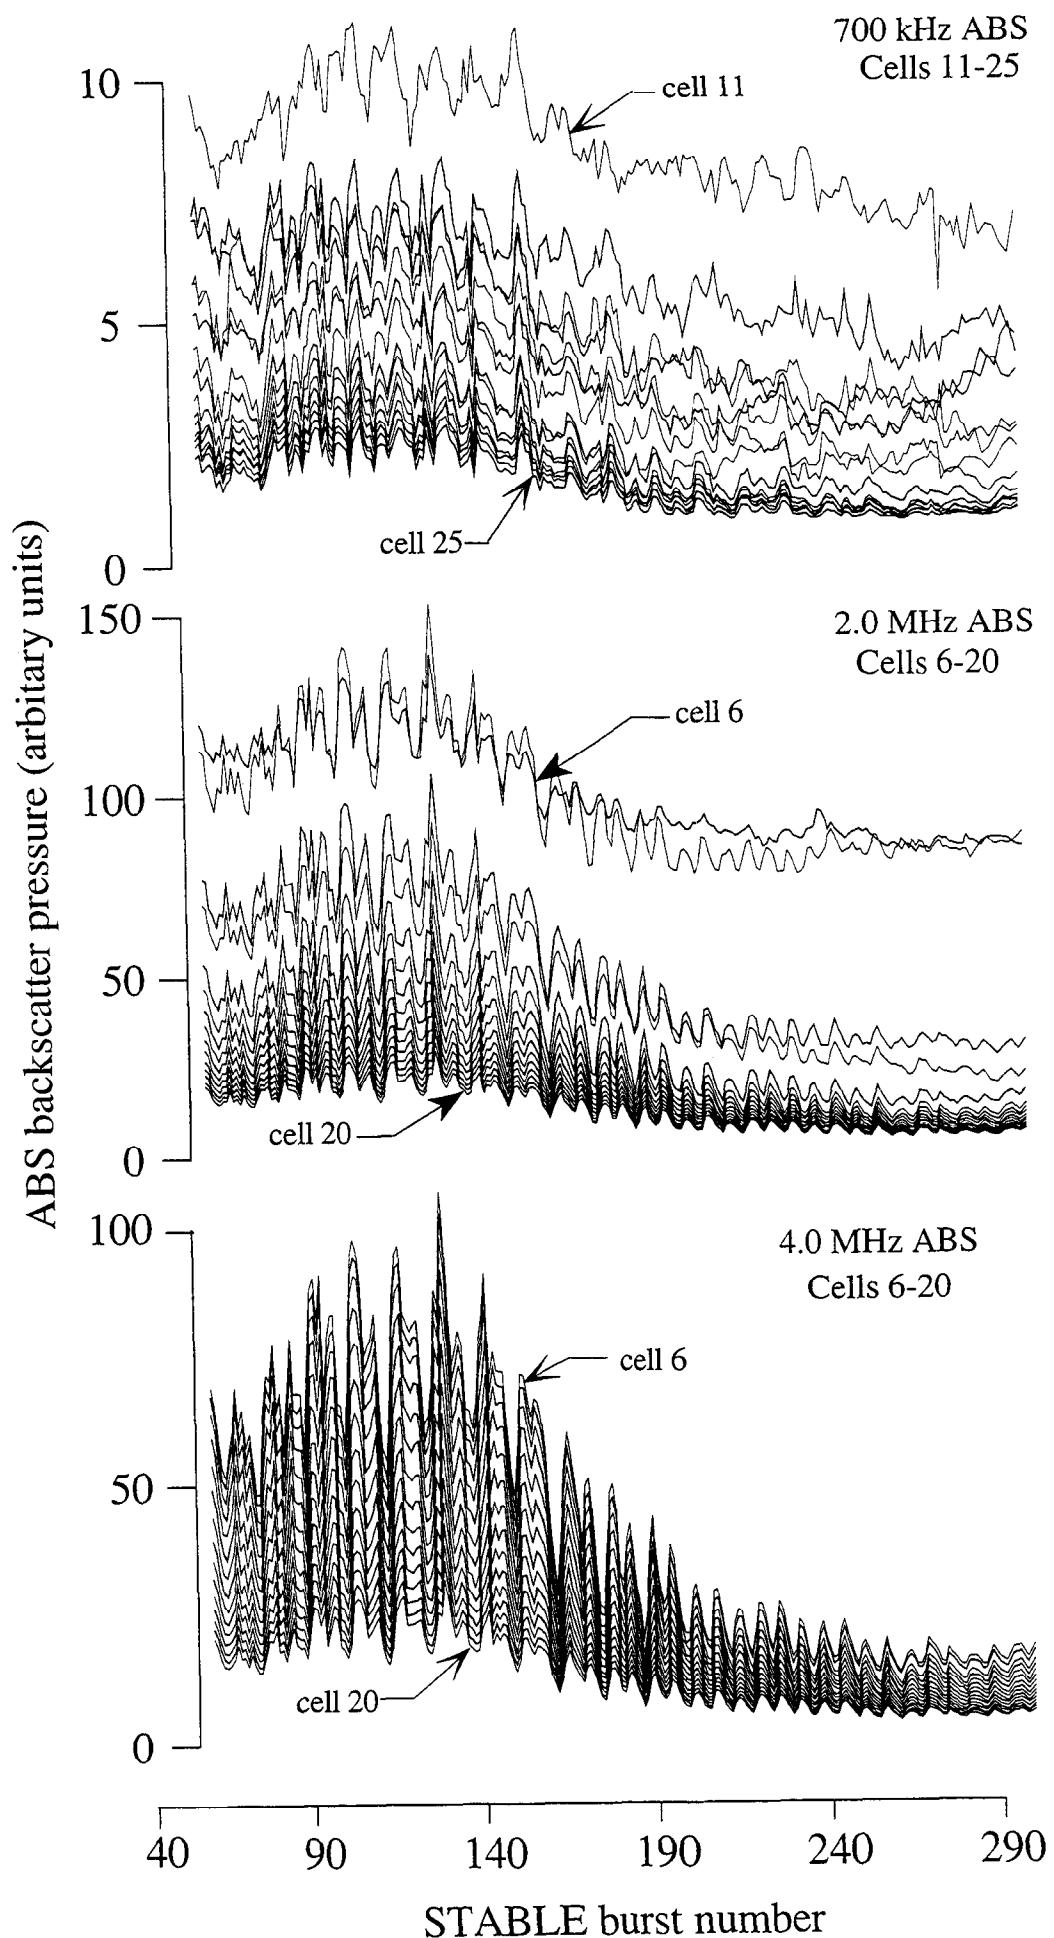

Figure 25 Burst average ABS observations of suspended sediments from: (a) 700 KHz (cells 11-25); (b) 2.0 MHz (cells 6-20); and (c) 4.0 MHz (cells 6-20).

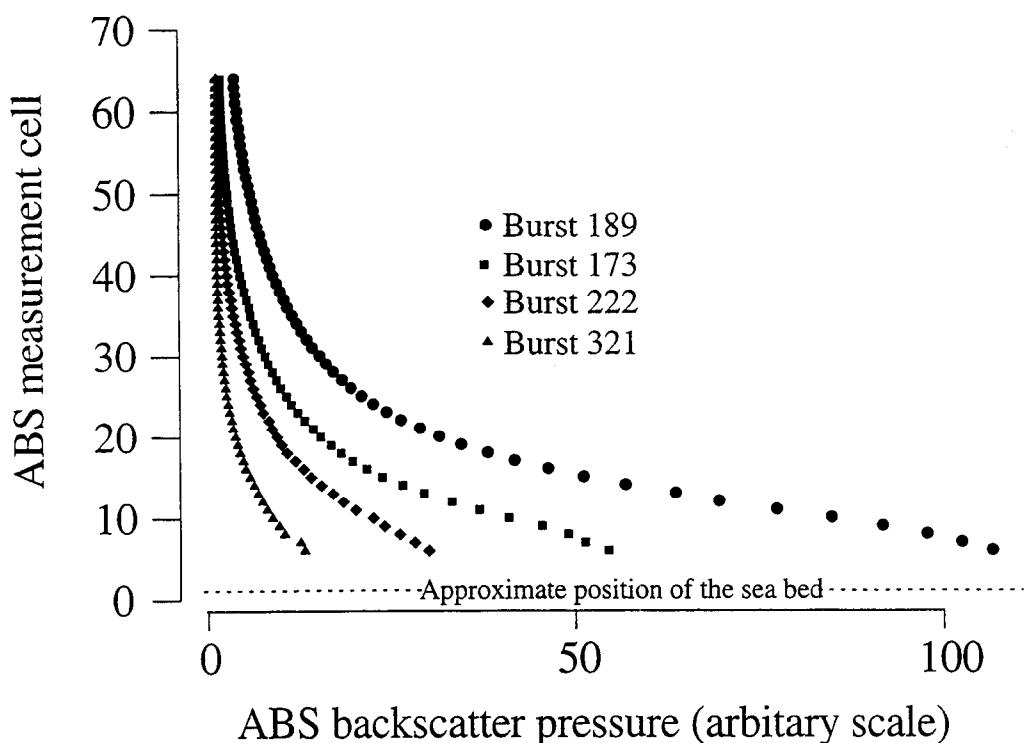

Figure 26 *Burst average ABS suspended sediment concentration profiles, bursts 89,173, 222 and 321.*

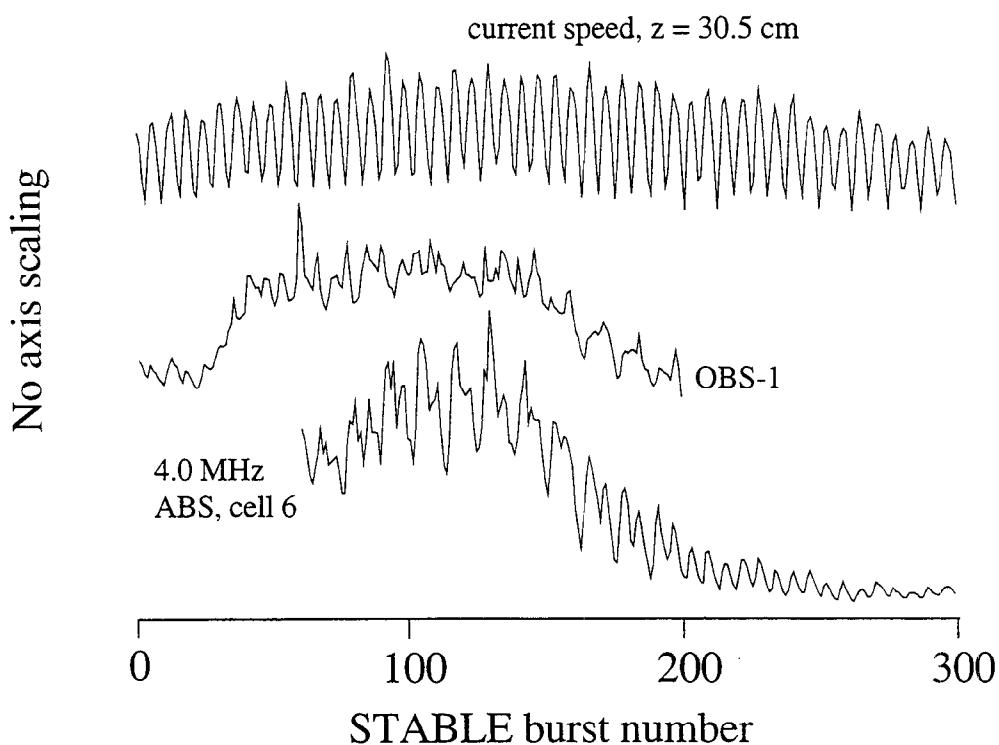

Figure 27 *Time series plots of burst average current speed, OBS ($z = 30.5$ cm) and ABS 4.0 MHz, measurement cell 6).*

| Header | Description | z | Units |
|-----------|---|---------|------------------------------------|
| Bst. No. | STABLE burst number | - | - |
| Date | Date of STABLE burst | - | - |
| Time | Time of STABLE burst | - | - |
| u-t | Burst average horizontal 'fore-aft' flow component | 60.3 cm | (cm/s) |
| v-t | Burst average horizontal 'port-starboard' flow component | 60.3 cm | (cm/s) |
| speed-t | Burst average current speed | 60.3 cm | (cm/s) |
| dir-t | Burst average current direction re. STABLE | 60.3 cm | (deg.) |
| u-b | Burst average horizontal fore-aft flow component | 30.5 cm | (cm/s) |
| v-b | Burst average horizontal port-starboard flow component | 30.5 cm | (cm/s) |
| speed-b | Burst average current speed | 30.5 cm | (cm/s) |
| dir-b | Burst average current direction re. STABLE | 30.5 cm | (deg) |
| uw-b | Burst average Reynolds stress $\overline{u'w'}$ | 30.5 cm | (cm ² /s ²) |
| vw-b | Burst average Reynolds stress $\overline{v'w'}$ | 30.5 cm | (cm ² /s ²) |
| uv-b | Burst average Reynolds stress $\overline{u'v'}$ | 30.5 cm | (cm ² /s ²) |
| Rstress-b | Burst average stress magnitude utilising the Reynolds stress method i.e. $(\overline{u'w'}^2 + \overline{v'w'}^2)^{0.5} = \tau/\rho$ | 30.5 cm | (cm ² /s ²) |
| dir-S-b | Burst average stress direction i.e. $\tan^{-1}(\overline{v'w'} / \overline{u'w'})$ | 30.5 cm | (deg.) |
| U*(R)-b | Burst average shear velocity utilising the Reynolds stress method i.e. $(\tau/\rho)^{0.5}$ | 30.5 cm | (cm/s) |
| U*TKE-b | Burst average shear velocity utilising the Reynolds stress method i.e. $0.19 * (1/2(\overline{u'}_{t+w} + \overline{v'}_{t+w} + \overline{w'}_{t+w}))$, waves included | 30.5 cm | (cm/s) |
| uw-t | Burst average Reynolds stress $\overline{u'w'}$ | 60.3 cm | (cm ² /s ²) |
| vw-t | Burst average Reynolds stress $\overline{v'w'}$ | 60.3 cm | (cm ² /s ²) |
| uv-t | Burst average Reynolds stress $\overline{u'v'}$ | 60.3 cm | (cm ² /s ²) |
| Rstress-t | Burst average stress magnitude utilising the Reynolds stress method i.e. $(\overline{u'w'}^2 + \overline{v'w'}^2)^{0.5} = \tau/\rho$ | 60.3 cm | (cm ² /s ²) |
| dir-S-t | Burst average stress direction i.e. $\tan^{-1}(\overline{v'w'} / \overline{u'w'})$ | 60.3 cm | (deg.) |
| U*(R)-t | Burst average shear velocity utilising the Reynolds stress method i.e. $(\tau/\rho)^{0.5}$ | 60.3 cm | (cm/s) |
| U*TKE-t | Burst average shear velocity utilising the Reynolds stress method i.e. $0.19 * (1/2(\overline{u'}_{t+w} + \overline{v'}_{t+w} + \overline{w'}_{t+w}))$, waves included | 60.3 cm | (cm/s) |
| Ustar-P | Burst average shear velocity, ECM log-profile method | - | (cm/s) |
| Z0-P | Burst average apparent bed roughness, ECM log-profile method | - | (cm) |
| ub-wave | Burst average variance in u' time series attributable to waves | 30.5 cm | (cm ² /s ²) |
| ub-turb | Burst average variance in u' time series attributable to turbulence | 30.5 cm | (cm ² /s ²) |
| vb-wave | Burst average variance in v' time series attributable to waves | 30.5 cm | (cm ² /s ²) |

11.0 Appendix I Definition of terms in the Microsoft Excel data base STABLE.xls

| Header | Description | z | Units |
|----------|---|---------|------------------------------------|
| vb-turb | Burst average variance in v' time series attributable to turbulence | 30.5 cm | (cm ² /s ²) |
| wb-wave | Burst average variance in w' time series attributable to waves | 30.5 cm | (cm ² /s ²) |
| wb-turb | Burst average variance in w' time series attributable to turbulence | 30.5 cm | (cm ² /s ²) |
| b-TKE-U* | Burst average shear velocity utilising the TKE method i.e. $0.19 * (1/2(\bar{u'}_t + \bar{v'}_t + \bar{w'}_t))$, waves excluded | 30.5 cm | (cm/s) |
| RMS-w-b | RMS wave orbital speed i.e. $(\bar{u'}_w^2 + \bar{v'}_w^2)^{0.5}$ | 30.5 cm | (cm/s) |
| DIR-w-b | Burst average wave direction i.e. $\tan^{-1}(\bar{v'}_w / \bar{u'}_w)$ | 30.5 cm | (deg.) |
| ut-wave | Burst average variance in u' time series attributable to waves | 60.3 cm | (cm ² /s ²) |
| ut-turb | Burst average variance in u' time series attributable to turbulence | 60.3 cm | (cm ² /s ²) |
| vt-wave | Burst average variance in v' time series attributable to waves | 60.3 cm | (cm ² /s ²) |
| vbt-turb | Burst average variance in v' time series attributable to turbulence | 60.3 cm | (cm ² /s ²) |
| wt-wave | Burst average variance in w' time series attributable to waves | 60.3 cm | (cm ² /s ²) |
| wt-turb | Burst average variance in w' time series attributable to turbulence | 60.3 cm | (cm ² /s ²) |
| t-TKE-U* | Burst average shear velocity utilising the TKE method i.e. $0.19 * (1/2(\bar{u'}_t + \bar{v'}_t + \bar{w'}_t))$, waves excluded | 60.3 cm | (cm/s) |
| RMS-w-t | RMS wave orbital speed i.e. $(\bar{u'}_w^2 + \bar{v'}_w^2)^{0.5}$ | 60.3 cm | (cm/s) |
| DIR-w-t | Burst average wave direction i.e. $\tan^{-1}(\bar{v'}_w / \bar{u'}_w)$ | 60.3 cm | (deg.) |
| u/U*-b | Burst average normalised RMS turbulence intensity (u') | 30.5 cm | (cm/s) |
| u/U*-t | Burst average normalised RMS turbulence intensity (u') | 60.3 cm | (cm/s) |
| v/U*-b | Burst average normalised RMS turbulence intensity (v') | 30.5 cm | (cm/s) |
| v/U*-t | Burst average normalised RMS turbulence intensity (v') | 60.3 cm | (cm/s) |
| w/U*-b | Burst average normalised RMS turbulence intensity (w') | 30.5 cm | (cm/s) |
| w/U*-t | Burst average normalised RMS turbulence intensity (w') | 60.3 cm | (cm/s) |
| Cd-b-RS | Burst average drag coefficient from Reynolds stress shear velocity estimates i.e. U_*^2 / S_{30}^2 | 30.5 cm | (-) |
| Cd-t-RS | Burst average drag coefficient from Reynolds stress shear velocity estimates i.e. U_*^2 / S_{30}^2 | 60.3 cm | (-) |
| Cd-b-TKE | Burst average drag coefficient from TKE shear velocity estimates i.e. U_*^2 / S_{30}^2 | 30.5 cm | (-) |
| Cd-t-TKE | Burst average Cd from TKE i.e. U_*^2 / S_{60}^2 | 60.3 cm | (-) |
| Za-b-RS | Burst average apparent bed roughness from RS shear velocity estimates i.e. $z \exp(-k/C_z^{0.5})$ | 30.5 cm | (cm) |
| Za-t-RS | Burst average apparent bed roughness from RS shear velocity estimates i.e. $z \exp(-k/C_z^{0.5})$ | 60.3 cm | (cm) |
| Za-b-TKE | Burst average apparent bed roughness from TKE shear velocity estimates i.e. $z \exp(-k/C_z^{0.5})$ | 30.5 cm | (cm) |

11.0 Appendix 1 Definition of terms in the Microsoft Excel data base STABLE.xls

| Header | Description | z | Units |
|----------|--|----------|------------------------------------|
| Za-t-TKE | Burst average apparent bed roughness from TKE shear velocity estimates i.e. $z \exp(-k_z/C_z^{0.5})$ | 60.3 cm | (cm) |
| RMSw/S-b | Ratio of RMS wave orbital speed: current speed | 30.5 cm | (-) |
| RMSw/S-t | Ratio of RMS wave orbital speed: current speed | 60.3 cm | (-) |
| E/S**2-b | Ratio of turbulent kinetic energy: current speed ² | 30.5 cm | (-) |
| E/S**2-t | Ratio of turbulent kinetic energy: current speed ² | 60.3 cm | (-) |
| Depth | Burst average water depth | 174.5 cm | (m) |
| R1 | Burst average current speed rotor 1 | 39 cm | (cm/s) |
| R2 | Burst average current speed rotor 2 | 57 cm | (cm/s) |
| R3 | Burst average current speed rotor 3 | 75 cm | (cm/s) |
| R4 | Burst average current speed rotor 4 | 93 cm | (cm/s) |
| Z0-rot | Burst average apparent bed roughness from log-profile (rotors) | - | (cm) |
| C100 | Burst average drag coefficient, rotor log-profile i.e. U_*^2 / Rz^2 | - | (-) |
| U*-R | Burst average shear velocity, rotor log-profile | - | (cm/s) |
| Tau-R | Burst average shear stress, rotor log-profile | - | (cm ² /s ²) |
| vane | Burst average current direction recorded by STABLE vane | 107.5 cm | (degrees) |
| compass | Burst average rig heading from onboard STABLE compass | - | |
| OBS-1 | Burst average SPM concentration | 30.5 cm | - |
| OBS-1 | Burst average SPM concentration | 60.3 cm | - |
| 700(9) | Burst average SPM concentration, 700 kHz ABS device | cell 9 | - |
