I. OVERVIEW

This report presents the activities undertaken by the Centre for Ecology and Hydrology (CEH-Wallingford) as part of the EcoEPI Follow-up contract. The role of CEH was to quantify the influence of wastewater inputs based on a national dataset of sewage treatment works (STWs) location and characteristics. Within this project, there were 307 catchments selected across England and Wales, for each catchment a weighted population contribution to the effluent load was derived and existing LF2K-WQX concentration predictions for steroid oestrogens included.

II. APPROACH

The work carried within this study was achieved mainly using the software ArcGIS.

II.1 Overview of the GIS data available

Within the initial study, the 307 sites selected in the project were mapped by Waterborne Environmental (USA), who provided a catchment boundaries shapefile. CEH then provided for each catchment the total number of STWs discharging within the catchment, the total dry weather flow (DWF) discharged in the catchment ($m^3 d^{-1}$) and the total population served by STWs within the catchment.

Within a recent project, CEH undertook a national-scale assessment of steroid oestrogen exposure across England and Wales on behalf of the Environment Agency. As part of this study, only those STWs contributing to 95% of the total DWF discharged above the tidal limit were included within the exposure assessment. Due to the time and resource constraints within this follow-up project, it was agreed with Cranfield University that the new variables would be derived using this reduced river network and reduced STW dataset.

II.2 Methodology

II.2.1 Weighted Population contribution

As mentioned previously, only those STWs contributing to 95% of the total DWF discharged above the tidal limit are included in this follow-up project.

The main task within this project was to derive a weighted population contribution to the chemical load for each STW within the catchment. These individual STW contribution were then summed to obtain a variable representative of the total contributing load (CL) to the catchment outlet. The CL accounted for losses due to biodegradation within the water column between the discharge point and the catchment outlet.

Thus three methods were proposed:

- Method 1a: the surrogate of the contributing load CL_1 is based on inverse distance weighing:

$$CL_1 = \sum_{i=1}^n \frac{Pop_i}{L_i}$$

Where:

- n is the number of STWs within the catchment
- Pop_i is the population served by STW i .
- L_i is the distance (km) between STW i and the catchment outlet, if $L_i < 1 \Rightarrow L_i = 1$

Within this method a minimum distance of 1 km was allowed in the calculations. This was because small distances provided a much higher weighted population than the actual population served.

- Method 1b: the surrogate of the contributing load CL_1 is based on inverse distance weighing:

$$CL_1 = \sum_{i=1}^n \frac{Pop_i}{L_i}$$

Where:

- n is the number of STWs within the catchment
- Pop_i is the population served by STW i .
- L_i is the distance (km) between STW i and the catchment outlet.

Within this method there was no lower limit on the distance used, because STW very close to the point of interest might well have a large impact on the ecology of that site (much greater than other STWs in the catchment).

- Method 2: the surrogate of the contributing load CL_2 reflects the calculation of in-stream concentration for a degradable chemical.

$$CL_2 = \sum_{i=1}^n Pop_i \times e^{-1/L_i}$$

Where:

- n is the number of STWs within the catchment
- Pop_i is the population served by STW i .
- L_i is the distance (km) between STW i and the catchment outlet,

The selection of appropriate STWs in each catchment was done within ArcGIS using the “Select by location...” functionality. The distance between STWs and catchment outlet were then calculated using the “closest facility” ArcGIS functionality, which provides the distance between 2 points based upon a user provided network. The actual calculations of CL_1 and CL_2 were done within Excel.

II.2.2 Existing predicted concentrations for steroid oestrogens

In order to assess the risk of fish intersex induced by steroid estrogens, Williams *et al.* (2009) predicted estrone (E_1), estradiol (E_2) and ethinylestradiol (EE_2) concentrations in surface waters across England and Wales, using the LF2000-WQX (LowFlows2000 Water Quality eXtension) model. LF2000-WQX is a mixed deterministic and stochastic model that combines hydrological models and water-quality models to produce spatially explicit statistical distributions of “down-the-

“drain” chemicals in surface waters across England and Wales (Williams *et al.*, 2009). The output of the model is a shapefile containing a river network split into reaches of variable length for which the downstream predicted concentrations are provided in terms of a series of statistics: mean, standard deviation and 90th percentile.

Within the present project, for each catchment the closest downstream concentration is supplied. The appropriate reach containing the catchment outlet was selected using the ArcGIS “Select by location...” functionality. As mentioned above, the reaches within the LF2000-WQX model are of variable length and the model assumes the reaches to be well mixed, therefore in reality there might be a difference between the concentration at the point of interest and the value given by the model for the whole reach.

III. RESULTS

An Excel document named ‘WEI_WS_95DWF_Followup’ was generated, based on the “WEI_WS_100DWF” shapefile delivered within the original EcoEpi project. The new worksheet contains the following fields, where the new fields are presented in bold:

- HydroID: field provided by Waterborne.
- Name: Unique catchment Id (provided by Waterborne).
- Shape_Leng: catchment perimeter (provided by Waterborne).
- Shape_Area: Catchment area (provided by Waterborne).
- Nb_STW: Number of STWs discharging within the catchment.
- TotDWF_M3D: Total DWF discharged into the catchment, in m³d⁻¹.
- Tot_RES: Total population served by STWs in the catchment.
- **95%_DWF**: DWF discharged in the catchment by those STWs contributing to 95% of the total DWF discharged above the tidal limit, in m³d⁻¹.
- **95%_Res**: Population served in the catchment by those STWs contributing to 95% of the total DWF discharged above the tidal limit.
- **95%_Nb_STW**: Number of STWs in the catchment that contribute to 95% of the total DWF discharged above the tidal limit.
- **CL1a**: Surrogate of the contributing load as defined by Method 1a.
- **CL1b**: Surrogate of the contributing load as defined by Method 1b.
- **CL2**: Surrogate of the contributing load as defined by Method 2.
- **EE2_Mean**: Predicted mean concentration for ethinylestradiol in ng/L.
- **EE2_SD**: Predicted standard deviation for ethinylestradiol in ng/L.
- **EE2_90th**: Predicted 90th percentile (concentration exceeded 10% of the time) for ethinylestradiol in ng/L.
- **E2_Mean**: Predicted mean concentration for estradiol in ng/L.
- **E2_SD**: Predicted standard deviation for estradiol in ng/L.
- **E2_90th**: Predicted 90th percentile (concentration exceeded 10% of the time) for estradiol in ng/L.
- **E1_Mean**: Predicted mean concentration for estrone in ng/L.
- **E1_SD**: Predicted standard deviation for estrone in ng/L.
- **E1_90th**: Predicted 90th percentile (concentration exceeded 10% of the time) for estrone in ng/L.

Some of the new contents (“Name” + some fields in bold) of the attribute table are presented in Appendix 1: only the mean concentrations for each steroid estrogen are presented in the table to save space (all data are in the spreadsheet).

Amongst the 307 catchments, there were five for which no STW data were available within the previous analysis when 100% of DWF was included, details of these are provided in the previous report. Amongst the remaining 298 catchments, there were five catchments for which the catchment outline as defined by Waterborne Environmental (USA) using the DEM data provided by CEH were wrong. These errors are most likely due to issues within the DEM dataset. The problematic catchments are presented in Appendix 2; for these 5 catchments, CL values could not be derived as the river network did not match the catchment outline.
