Note : much of the hydrometric data featured in this report is provisional; the Foot and Mouth outbreak has also

# restricted the amount of data available. <br> Hydrological summary for the United Kingdom 

## General

March rainfall was close to the long term average for the UK as a whole, but regional variations were large; much of southern England was again very wet. Provisional figures indicate that rainfall for EW over the last seven months closely matches the wettest seven-month period on record. River flows during March were mostly within in the normal range in northern and western catchments but spate conditions continued in southern Britain. Runoff was outstanding in many spring-fed rivers and the protracted episode of 'clear-water' flooding in permeable catchments continued as groundwater levels remained close to term maxima over wide areas. Reservoir stocks and overall groundwater resources are exceptionally healthy for the early spring but the flood risk will continue until accelerating evaporation rates help dryout the soils across what remains a largely saturated landscape. The chance of further floodplain inundations is of particular concern to the agricultural community given the current restrictions on livestock movement.

## Rainfall

As with much of the preceding autumn and winter, March rainfall patterns served to moderate the normal NW-SE rainfall gradient across the UK. In a zone extending from the western Highlands to Northern Ireland some localities recorded less than $35 \%$ of the average monthly rainfall. By contrast, parts of the South-East reported more than 200\%; March rainfall in Sussex was higher than in much of the Highland Region. Substantial parts of the English lowlands reported their seventh successive wet month, and rainfall accumulations in the 3-7 month timeframes are remarkable. Whilst provisional figures suggest that Northern Ireland had its driest start to the year (Jan-Mar) for 36 years, and Scotland its second driest in the last 31 years, rainfall records continue to be broken for England and Wales. Rainfall over the last six months substantially exceeds the previous highest (that for 1929/30) for the winter half-year (Oct-Mar) in the Climate Research Unit's 235-year E\&W rainfall series and the September-March total closely matches the maximum seven-month total for any start month (1852/53). In the modern era, only in 1960/ 61 have half-year rainfall totals approaching those recently experienced. Over the winter half-year large parts of the English Lowlands have received well over $150 \%$ of average rainfall. More notably, throughout much of the South-East, the 6-month total exceeds the annual average, by a wide margin in parts of the Southern and Thames regions; for the Thames catchment (above Kingston) rainfall accumulations since last August are unprecedented (for any start month) in a series from 1883.

## River Flows

March river flows in most maritime western and northern catchments were generally within the normal early spring range but rainfall and snowmelt produced some significant spates (e.g. on the $6^{\text {th }}$ in north-east England). Generally however monthly runoff totals were below average - the River Luss (draining from the Scottish Highlands) reported its lowest March flow on record and in NI the River Bush recorded its lowest flow for 28 years. Throughout most of southern England however, exceptional runoff rates continued. Many southern rivers (including the Blackwater, Lymington and Otter, each with records > 38 yrs) established new maximum March runoff totals. Abundant spring outflows continued and the outstanding baseflow contributions made for record discharge rates in a number of groundwater-fed streams (e.g. the Ewelme

Brook in the Chilterns). Mean March flows in the Mimram (like those for February also) exceeded the previous maximum - for any month - in a record from 1952. The recent redefinition of high flow regimes- in permeable catchments especially - is most evident in runoff accumulations spanning up to six months. For the year thus far, runoff in the Itchen exceeds the previous maximum by more than $25 \%$ and the singular nature of recent hydrological conditions is underlined by the winter half-year runoff totals. In records of 116 and 118 years respectively, new 6-month runoff maxima have been established on the Lee and Thames. For gauging stations with shorter records, previous maxima have been eclipsed by very wide margins (e.g. around $60 \%$ for the Mole). With catchments still saturated at month end the risk of further flooding remained very real, across southern Britain in particular.

## Groundwater

Foot and Mouth restrictions severely affected the collection of groundwater level data during March. Nonetheless, the impact of the historically outstanding recharge totals (over four times the average in some eastern areas) over the winter half-year remains very evident - in terms of exceptionally high groundwater levels, record spring outflows, the migration of stream sources high into the headwaters, and very protracted clear-water flooding. Although there has been some decline from record December peaks (e.g. at Compton) in the more responsive aquifer units, further heavy pulses of recharge have maintained exceptionally high groundwater levels in the Chalk. Levels continued to rise through March in many eastern outcrop areas (and in the Chilterns) where the commonly exceed previous maxima by significant margins (e.g. at Redlands and Stonor). There is no close parallel - in a 118-year record - for the recent rapid recovery in the deep Therfield well; levels now stand at their highest since the First World War. Pumping is being used to help reduce groundwater levels in areas subject to significant flooding (e.g. in the upper Pang catchment). Recessions were apparent in some northern aquifers (e.g. the Carboniferous limestone at Alstonfield) but unprecedented levels still characterise many PermoTriassic sandstones outcrops. Across England as a whole, there is no close modern precedent to the scale and duration of the 2000/2001 groundwater flooding.

## Key

January 2001 - March 2001
October 2000 - March 2001

## Rainfall accumulation maps

The moderation in the north-west to south-east rainfall gradient across the UK is particularly evident in the JanuaryMarch rainfall patterns. Return periods associated with the winter half-year rainfall totals exceed 200 years throughout much of the English Lowlands; these help to explain the remarkable increase in groundwater levels over the period since September 2000.

## River flow 。 . River flow

## River flows - March 2001

*Comparisons based on percentage flows alone can be misleading. A given percentage flow can represent extreme drought conditions in permeable catchments where flow patterns are relatively stable but be well within the normal range in impermeable catchments where the natural variation in flows is much greater. Note: the period of record on which these percentages are based varies from station to station.

## Groundwater . . . Groundwater

Groundwater levels normally rise and fall with the seasons, reaching a peak in the spring following replenishment through the winter (when evaporation losses are low and soil moist). They decline through the summer and early autumn. This seasonal variation is much reduced when the aquifer is confined below overlying impermeable strata. The monthly max., min. and mean levels are displayed in a similar style to the river flow hydrographs. Note that most groundwater levels are not measured continuously - the latest recorded levels are listed overleaf.

* No March/ April groundwater levels available.

## Groundwater . . . Groundwater

## Groundwater levels - March 2001

The rankings are based on a comparison between the average level in the featured month (but often only single readings are available) and the average level in each corresponding month on record. They need to be interpreted with caution especially when groundwater levels are changing rapidly or when comparing wells with very different periods of record. Rankings may be omitted where they are considered misleading.

Ireland
()figures in parentheses relate to gross storage

- denotes reservoir groups *last occurrence
**updated gross capacity
Details of the individual reservoirs in each of the groupings listed above are available on request. The featured reservoirs may not be representative of the storage conditions across each region; this can be particularly important during droughts. The minimum storage figures relate to the 1988-2000 period only (except for West of Scotland where data commence in 1994). In some gravity-fed reservoirs (e.g. Clywedog) stocks are kept below capacity during the winter to provide scope for flood attenuation purposes.

## Location map ... Location map

# National Hydrological Monitoring Programme 

The National Hydrological Monitoring Programme was instigated in 1988 and is undertaken jointly by the Centre for Ecology and Hydrology, Wallingford (formerly the Institute of Hydrology - IH) and the British Geological Survey (BGS). Financial support for the production of the monthly Hydrological Summaries is provided by the Department of the Environment, Transport and the Regions, the Environment Agency (EA), the Scottish Environment Protection Agency (SEPA), the Rivers Agency (RA) in Northern Ireland, and the Office of Water Services (OFWAT).

## Data Sources

River flow and groundwater level data are provided by the regional divisions of the EA (England and Wales) and SEPA (Scotland), data for Northern Ireland are provided by the Rivers Agency and the Department of the Environment (NI). In all cases the data are subject to revision following validation (flood and drought data in particular may be subject to significant revision).

Reservoir level information is provided by the Water Service Companies, the EA, the West of Scotland and East of Scotland Water Authorities, and the Northern Ireland Water Service.

The National River Flow Archive (maintained by CEH Wallingford) and the National Groundwater Level Archive (maintained by BGS) provide the historical perspective within which to examine contemporary hydrological conditions.

## Rainfall

Most rainfall data are provided by The Met. Office (address opposite). To allow better spatial differentiation the rainfall data for Britain are presented for the regional divisions of the precursor organisations of the EA and SEPA. Following the discontinuation of The Met. Office's CARP system in July 1998, the areal rainfall figures have been derived using several procedures, including initial estimates based on MORECS*. Recent figures have been produced by The Met. Office, National Climate Information Centre (NCIC), using a technique similar to CARP. An initiative is underway with The Met. Office to provide more accurate areal figures and, since October 1999, to include more raingauges in the analysis. A significant number of additional monthly rainfall totals are currently being provided by the Environment Agencies; over the coming months further monthly
raingauge totals will be included for selected regions. Until the access to these additional data has stabilised the regional figures (and the return periods associated with them) should be regarded as a guide only.
*MORECS is the generic name for the Meteorological Office services involving the routine calculation of evaporation and soil moisture throughout Great Britain.

The National Hydrological Monitoring Programme depends on the active cooperation of many data suppliers. This cooperation is gratefully acknowledged; the Hydrological Summaries for the autumn and early winter of 2000/2001, in particular, stand as a testimony to the assistance provided by many hydrometric personnel working in exceptionally challenging circumstances.

## Subscription

Subscription to the Hydrological Summaries costs £48 per year. Orders should be addressed to:
