Note : much of the hydrometric data featured in this report is provisional; the Foot and Mouth outbreak has also restricted the amount of data available.

# Hydrological summary for the United Kingdom <br> \section*{General} 

February was decidedly wintry, particularly in northern Britain which experienced severe blizzard conditions. Nationally, precipitation totals fell considerably short of those registered in the autumn and early winter months, but the monthly average was exceeded once again. Accumulated rainfall totals are remarkably high and the resulting abundance of runoff and recharge has established a major new hydrological benchmark, for England and Wales especially. Most catchments remained close to saturation through February and Flood Watches were again common. Spate conditions have been remarkably persistent in the English lowlands; in part, this reflects unprecedented groundwater levels. Groundwater flooding was extensive and - by its nature - protracted, causing problems in areas remote from the lowlying floodplains. Reservoir contents remain close to capacity and the water resources outlook is very healthy, but the flood risk will remain high until accelerating evaporation rates help to dry out sodden catchments.

## Rainfall

Rigorous frontal systems continued to track across the UK in early February - the $7 / 8^{\text {th }}$ was especially wet (Folkestone reported 55 mm in 24 hours) - but high pressure became more dominant in mid-month and, with synoptic patterns favouring precipitation in eastern regions, rainfall in the west was modest thereafter. Provisional February rainfall totals exceed twice the monthly average in parts of northeast and south-east England; in the latter region some localities had their wettest February since 1951. By contrast parts of Northern Ireland (e.g. around Lough Neagh), and western Scotland reported less than $70 \%$. Away from these regions, winter (Dec-Feb) rainfall totals are considerably above average - notably so in most of southern Britain. Significantly in relation to the hydrological conditions of the last six months, the Sept-Feb total for the UK was the second highest (after 1994/95) in a series from 1900. Even more notably, the corresponding provisional total for England and Wales, has been exceeded (for any six month period) only during the winter of 1960/61 over the last 120 years. Six-month rainfall totals in the English lowlands are remarkable. Many areas in the South-East registered their sixth successive month with well above average rainfall. Over the Thames catchment, the Sept-Feb total vies with 1903 (May-Oct) as the wettest 6 -month sequence in a series from 1883. For catchments with areal rainfall records beginning in the last 40 years (a substantial majority), the abundance of rainfall has no recorded precedent. Large areas of the South-East have now received more than their annual average rainfall since the beginning of September 2000.

## River Flows

Limited precipitation, and the frozen condition of some upland catchments, contributed to modest runoff in parts of western Scotland and Northern Ireland during February. Elsewhere, runoff was generally well above average with further notable flood events adding to a remarkable cluster. Flooding returned to the South-East on the 8/9 ${ }^{\text {th }}$ (e.g. on the Cuckmere in E. Sussex) and the Thames (at Kingston) registered its third separate event in the last four months with a return period of five or more years - a unique circumstance in a record from 1883. February runoff totals were extraordinarily high in many lowland rivers fed largely from groundwater. The Mimram reported its highest runoff for any month in a series from 1952, the Lee exceeded its
previous February maximum in a 118-year record and runoff in most lowland rivers was close to the maximum. The even more outstanding 3 - and 6 -month runoff accumulations emphasise the singular nature of the hydrological conditions over the last half-year. The Dec-Feb runoff for the Itchen is substantially greater than any preceding 3-month accumulation and runoff since the beginning of September exceeds the mean annual average in over $80 \%$ of the index catchments across E\&W; it is approaching twice the annual average in some responsive catchments in the SouthEast (e.g the Mole). More than $40 \%$ of gauging stations (in E\&W) are estimated to have eclipsed previous maximum flows over the last six months and the frequency of flood events has been without modern precedent.

## Groundwater

In percentage terms, the highest rainfall in February generally favoured the outcrop areas of the major aquifers; to an extent this is also true of the entire recharge season thus far. The unusual rainfall distribution (and its magnitude) is reflected in the autumn and winter effective rainfall totals - these are between three and four times the average in parts of the eastern and southern Chalk. Rapid drainage from high level springs and seepages has reduced groundwater levels in some of the more responsive aquifer units but, in the east particularly, the lagged water-table response to the late 2000 infiltration has rapidly gathered momentum. Recoveries have been dramatic at Therfield and Little Bucket which is thought to have overflowed for the first time in February. Many Chalk wells and boreholes (including Redlands, Stonor Park and Lime Kiln Way) exceeded their previous maxima (for any month) during February. Unprecedented levels were also reported for the Permo-Triassic sandstones (e.g. at Heathlanes and Nuttalls Farm), and levels remain above previous maxima in the Magnesian Limestone (Peggy Ellerton). Several recent winters (e.g. 1989/90, 1993/94 and 1994/ 95) have seen exceptionally high groundwater levels but the extent and persistence of 'clear-water' flooding and the magnitude of spring outflows sets 2000/2001 apart - the historical range of recorded groundwater level variation has been extended in many areas over the last few months.

September 2000 - February 2001

## Rainfall accumulation maps

After three wet winters in succession, Northern Ireland and Scotland both recorded below average Dec-Feb rainfall totals; relative to the long term average the Highland Region was especially dry. A notable recent moderation in the normal north-west to south-east rainfall gradient across the country is evident the modest margin by which the Sept 2000-Feb 2001 rainfall for the Highland Region exceeds that for the EA Southern Region.

## River flows - February 200I

*Comparisons based on percentage flows alone can be misleading. A given percentage flow can represent extreme drought conditions in permeable catchments where flow patterns are relatively stable but be well within the normal range in impermeable catchments where the natural variation in flows is much greater. Note: the period of record on which these percentages are based varies from station to station.

## River flow . . . River flow

## Monthly river flow hydrographs

The river flow hydrographs show the monthly mean flow (bold trace), the long term average monthly flow (dotted trace) and the maximum and minimum flow prior to 1998 (shown by the shaded areas). Monthly flows falling outside the maximum/minimum range are indicated where the bold trace enters the shaded areas.

## Groundwater <br> Groundwater

Groundwater levels normally rise and fall with the seasons, reaching a peak in the spring following replenishment through the winter (when evaporation losses are low and soil moist). They decline through the summer and early autumn. This seasonal variation is much reduced when the aquifer is confined below overlying impermeable strata. The monthly max., min. and mean levels are displayed in a similar style to the river flow hydrographs. Note that most groundwater levels are not measured continuously - the latest recorded levels are listed overleaf.

Note. Due to the impact of abstraction on groundwater levels at The Holt borehole, it has been replaced as an index site by the Stonor Park well.

## Groundwater . . . Groundwater

## Groundwater levels - February 2001

The rankings are based on a comparison between the average level in the featured month (but often only single readings are available) and the average level in each corresponding month on record. They need to be interpreted with caution especially when groundwater levels are changing rapidly or when comparing wells with very different periods of record. Rankings may be omitted where they are considered misleading.

()figures in parentheses relate to gross storage

- denotes reservoir groups *last occurrence
**updated gross capacity
Details of the individual reservoirs in each of the groupings listed above are available on request. The featured reservoirs may not be representative of the storage conditions across each region; this can be particularly important during droughts. The minimum storage figures relate to the $1988-2000$ period only (except for West of Scotland where data commence in 1994). In some gravity-fed reservoirs (e.g. Clywedog) stocks are kept below capacity during the winter to provide scope for flood attenuation purposes.

# National Hydrological Monitoring Programme 

The National Hydrological Monitoring Programme was instigated in 1988 and is undertaken jointly by the Centre for Ecology and Hydrology, Wallingford (formerly the Institute of Hydrology - IH) and the British Geological Survey (BGS). Financial support for the production of the monthly Hydrological Summaries is provided by the Department of the Environment, Transport and the Regions, the Environment Agency (EA), the Scottish Environment Protection Agency (SEPA), the Rivers Agency (RA) in Northern Ireland, and the Office of Water Services (OFWAT).

## Data Sources

River flow and groundwater level data are provided by the regional divisions of the EA (England and Wales) and SEPA (Scotland), data for Northern Ireland are provided by the Rivers Agency and the Department of the Environment (NI). In all cases the data are subject to revision following validation (flood and drought data in particular may be subject to significant revision).

Reservoir level information is provided by the Water Service Companies, the EA, the West of Scotland and East of Scotland Water Authorities, and the Northern Ireland Water Service.

The National River Flow Archive (maintained by CEH Wallingford) and the National Groundwater Level Archive (maintained by BGS) provide the historical perspective within which to examine contemporary hydrological conditions.

## Rainfall

Most rainfall data are provided by The Met. Office (address opposite). To allow better spatial differentiation the rainfall data for Britain are presented for the regional divisions of the precursor organisations of the EA and SEPA. Following the discontinuation of The Met. Office's CARP system in July 1998, the areal rainfall figures have been derived using several procedures, including initial estimates based on MORECS*. Recent figures have been produced by The Met. Office, National Climate Information Centre (NCIC), using a technique similar to CARP. An initiative is underway with The Met. Office to provide more accurate areal figures and, since October 1999, to include more raingauges in the analysis. A significant number of additional monthly rainfall totals are currently being provided by the Environment Agencies; over the coming months further monthly
raingauge totals will be included for selected regions. Until the access to these additional data has stabilised the regional figures (and the return periods associated with them) should be regarded as a guide only.
*MORECS is the generic name for the Meteorological Office services involving the routine calculation of evaporation and soil moisture throughout Great Britain.

The Met. Office
Johnson House

Fax:01344854906
The National Hydrological Monitoring Programme depends on the active cooperation of many data suppliers. This cooperation is gratefully acknowledged; the Hydrological Summaries for the autumn and early winter of 2000/2001, in particular, stand as a testimony to the assistance provided by many hydrometric personnel working in exceptionally challenging circumstances.

## Subscription

Subscription to the Hydrological Summaries costs $£ 48$ per year. Orders should be addressed to:

Hydrological Summaries
CEH Wallingford
Maclean Building
Crowmarsh Gifford
Wallingford
Oxfordshire

[^0]:    The monthly rainfall figures* are copyright of The Met. Office and may not be passed on to any unauthorised person or organisation. All monthly totals since December 1998 are provisional (see page 12). The return period estimates are based on tables provided by the Meteorological Office (see Tabony, R.C., 1977, The variability of long duration rainfall over Great Britain, Scientific Paper No. 37) and relate to the specified span of months only (return periods may be up to an order of magnitude less if $n$-month periods beginning in any month are considered); RP estimates for Northern Ireland are based on the tables for north-west England. The tables reflect rainfall over the period 1911-70 and assume a stable climate. Artifacts in the England \& Wales and Scotland rainfall series can exaggerate the relative wetness of the recent past. "See page 12.
