# Hydrological summary for the United Kingdom 

## General

A dry interlude in late December provided a much-needed respite following one of the most remarkable hydrological episodes of modern times. The Oct-Dec period for England \& Wales was the second wettest three-month sequence in the last 200 years. Many new local and regional rainfall records have been established over the last four months. A further phase of extensive flooding during December confirmed the event as, overall, the most severe widespread flooding since 1947. As flows in many rivers declined from mid-month, groundwater levels continued a dramatic seasonal recovery - triggering groundwater flooding and exceptional outflows from high level springs. Some flood drawdown releases were made from reservoirs but overall stocks are still close to capacity. Entering 2001, catchments remained saturated and very vulnerable to further rainfall. Unusual though recent climate patterns have been, several broadly comparable wet episodes can be identified (e.g. the Oct-Jan periods of 1960/61, 1929/30 and 1852/53), and - as yet - most lengthy river flow and groundwater level series in E\&W do not exhibit any compelling climate-driven trend.

## Rainfall

December was the fourth successive month dominated by vigorous frontal systems. However, except for significant snowfall around the $27^{\text {th }}$, the final two weeks were relatively dry. Nonetheless, monthly rainfall totals comfortably exceeded the December average throughout most of the UK; parts of southern England again registered more than 200\% and in Northern Ireland, Bangor registered a very notable $270 \%$. A more appropriate measure of the singular conditions experienced since the early autumn is provided by the Sep-Dec and Oct-Dec rainfall totals. The UK registered its wettest Oct-Dec since 1930 and the three- and fourmonth totals are outstanding across much of the country see Table 1. Locally, the Sep-Dec totals approach the annual average in a few parts of the South-East (e.g. south of London). In relation to the period over which the bulk of UK river flow and groundwater data have been collected, the recent rainfall is unprecedented. Longer term rainfall accumulations are also remarkable. E\&W had its wettest nine-month period in 40 years and its second wettest year since 1903, as did the UK as a whole (1998 was marginally wetter).

## River flow

The major flooding experienced through the autumn continued well into December. Flood warnings were again common and many rivers reported their third (or more in responsive lowland catchments) notable flood peak in eight weeks. On the Hampshire Avon, for example, the Oct, Nov, and Dec peaks each rank amongst the highest five in the last 20 years. The Thames, in its middle reaches, reported its highest flow since 1947. From mid-month, recessions became established in many western and northern rivers and flows fell below average approaching year-end. By contrast, spates continued in permeable catchments as baseflows increased steeply - culminating in mid-Dec with a remarkable peak flow (return period $>200$ years) on the Itchen. Localised and more extensive groundwater flooding was common - in southern England particularly. Severe flooding was also reported for the Somerset Levels. The great majority of $\mathrm{E} \& \mathrm{~W}$ index gauging stations reported new
maximum Dec runoff totals, a few - including the Kennet, Itchen and Dorset Stour - were unprecedented for any month. An even more compelling testimony to the scale and duration of the flooding is provided by the Oct-Dec runoff totals. Catchments for which the accumulated runoff exceed previous maxima (for any start month) show a very wide distribution; they include the Tweed, Trent, Itchen, Brue and Welsh Dee - the latter in a record from 1937. Initial analyses suggest that the 50-day runoff total for $\mathrm{E} \& \mathrm{~W}$ as a whole over the period to midDec is the highest for at least 60 years (although peak runoff in March 1947 was higher, the flooding was of shorter duration). The outstanding flows since early Oct have ensured that runoff totals for 2000 are the highest on record for most index catchments in E\&W.

## Groundwater

Exceptionally high rates of infiltration continued until the third week of December, by which time recharge to most aquifer units had exceeded the full winter average - by a very wide margin in parts of the eastern Chalk. Steep recoveries have been a feature of several recent years (e.g. 89/90, $93 / 94$ and 97/98) but none matches the current episode. In the Chalk of the South Downs, the Chilgrove borehole began overflowing in November probably the earliest occurrence in a series from 1836 and December levels at Compton reached a new recorded peak in a series from 1894. Water-tables are now rising rapidly in the deeper, slowest responding wells - levels at Therfield during December exceeded the monthly average for the first time since 1995. Record high levels were reported from many wells and boreholes across the country - examples in the Permo-Triassic sandstones include Skirwith, Llanfair DC and Heathlanes, in each case a dramatic contrast to late-1997 when levels were at, or below, previous mimima. Overall groundwater resources in December are likely to have been without modern precedent. The rapidly rising water-table caused high level springs to break remarkably early in the winter, extending the lowland stream network into the headwaters of many 'dry' valleys.

The monthly rainfall figures* are copyright of The Met. Office and may not be passed on to any unauthorised person or organisation. All monthly totals since December 1998 are provisional (see page 12). The return period estimates are based on tables provided by the Meteorological Office (see Tabony, R.C., 1977, The variability of long duration rainfall over Great Britain, Scientific Paper No. 37) and relate to the specified span of months only (return periods may be up to an order of magnitude less if $n$-month periods beginning in any month are considered); RP estimates for Northern Ireland are based on the tables for north-west England. The tables reflect rainfall over the period 1911-70 and assume a stable climate. Artifacts in the England \& Wales and Scotland rainfall series can exaggerate the relative wetness of the recent past. "See page 12.

## Rainfall . . . Rainfall . . . Rainfall

Key
Percentage of
$1961-90$ average
Very wet

## Rainfall accumulation maps

Provisional data indicate that the September-December period was the wettest on record for England and Wales (in a series from 1766) and for Northern Ireland (from 1900). On an annual basis, the 2000 rainfall totals rank 8th wettest for E\&W, 11th wettest for Scotland (but a cluster of years over the last decade have been wetter), and 20th wettest for NI.

## River flows - December 2000

*Comparisons based on percentage flows alone can be misleading. A given percentage flow can represent extreme drought conditions in permeable catchments where flow patterns are relatively stable but be well within the normal range in impermeable catchments where the natural variation in flows is much greater. Note: the period of record on which these percentages are based varies from station to station.

## Monthly river flow hydrographs

The river flow hydrographs show the monthly mean flow (bold trace), the long term average monthly flow (dotted trace) and the maximum and minimum flow prior to 1997 (shown by the shaded areas). Monthly flows falling outside the maximum/minimum range are indicated where the bold trace enters the shaded areas.

| Clyde | 145 | $37 / 37$ |

## Groundwater

 Groundwater

Groundwater levels normally rise and fall with the seasons, reaching a peak in the spring following replenishment through the winter (when evaporation losses are low and soil moist). They decline through the summer and early autumn. This seasonal variation is much reduced when the aquifer is confined below overlying impermeable strata. The monthly max., min. and mean levels are displayed in a similar style to the river flow hydrographs. Note that most groundwater levels are not measured continuously - the latest recorded levels are listed overleaf.

Note. Due to the impact of abstraction on groundwater levels at The Holt borehole, it has been replaced as an index site by the Stonor Park well.

## Groundwater levels December 2000/January 2001

## Groundwater . . . Groundwater

## Groundwater levels - December 2000

The rankings are based on a comparison between the average level in the featured month (but often only single readings are available) and the average level in each corresponding month on record. They need to be interpreted with caution especially when groundwater levels are changing rapidly or when comparing wells with very different periods of record. Rankings may be omitted where they are considered misleading.

## National Hydrological Monitoring Programme

The National Hydrological Monitoring Programme was instigated in 1988 and is undertaken jointly by the Centre for Ecology and Hydrology, Wallingford (formerly the Institute of Hydrology - IH) and the British Geological Survey (BGS). Financial support for the production of the monthly Hydrological Summaries is provided by the Department of the Environment, Transport and the Regions, the Environment Agency (EA), the Scottish Environment Protection Agency (SEPA), the Rivers Agency (RA) in Northern Ireland, and the Office of Water Services (OFWAT).

## Data Sources

River flow and groundwater level data are provided by the regional divisions of the EA (England and Wales) and SEPA (Scotland), data for Northern Ireland are provided by the Rivers Agency and the Department of the Environment (NI). In all cases the data are subject to revision following validation (flood and drought data in particular may be subject to significant revision).

Reservoir level information is provided by the Water Service Companies, the EA, the West of Scotland and East of Scotland Water Authorities, and the Northern Ireland Water Service.

The National River Flow Archive (maintained by CEH Wallingford) and the National Groundwater Level Archive (maintained by BGS) provide the historical perspective within which to examine contemporary hydrological conditions.

## Rainfall

Most rainfall data are provided by The Met. Office (address opposite). To allow better spatial differentiation the rainfall data for Britain are presented for the regional divisions of the precursor organisations of the EA and SEPA. Following the discontinuation of The Met. Office's CARP system in July 1998, the areal rainfall figures have been derived using several procedures, including initial estimates based on MORECS*. Recent figures have been produced by The Met. Office, National Climate Information Centre (NCIC), using a technique similar to CARP. An initiative is underway with The Met. Office to provide more accurate areal figures and, since October 1999, to include more raingauges in the analysis. A significant number of additional monthly rainfall totals are currently being provided by the Environment Agencies; over the coming months further monthly
raingauge totals will be included for selected regions. Until the access to these additional data has stabilised the regional figures (and the return periods associated with them) should be regarded as a guide only.
*MORECS is the generic name for the Meteorological Office services involving the routine calculation of evaporation and soil moisture throughout Great Britain.

The National Hydrological Monitoring Programme depends on the active cooperation of many data suppliers. This cooperation is gratefully acknowledged; the Hydrological Summaries for the autumn and early winter of 2000/2001, in particular, stand as a testimony to the assistance provided by many hydrometric personnel working in exceptionally challenging circumstances.

## Subscription

Subscription to the Hydrological Summaries costs $£ 48$ per year. Orders should be addressed to:

Hydrological Summaries

[^0]:    Details of the individual reservoirs in each of the groupings listed above are available on request. The featured reservoirs may not be representative of the storage conditions across each region; this can be particularly important during droughts. The minimum storage figures relate to the 1988-2000 period only (except for West of Scotland where data commence in 1994). In some gravity-fed reservoirs (e.g. Clywedog) stocks are kept below capacity during the winter to provide scope for flood attenuation purposes.
