# Hydrological summary for the United Kingdom 

#### Abstract

\section*{General}

Floodplains form part of the natural province of rivers and, as such, are subject to periodic inundation. This fact, and its implications, have been dramatically underlined during the last 10 weeks. Heavy and sustained November rainfall provided the culmination to the wettest autumn for England and Wales in a record from 1766. The recorded range of cumulative rainfall, runoff totals, and autumn aquifer recharge rates, has been extended over a period which has witnessed flooding on a scale and duration which has few modern parallels. Most reservoir stocks are close to capacity and groundwater levels are approaching, or have exceeded, seasonal maxima over wide areas. Extensive sheets of floodwater have become a prominent, if temporary, feature of the landscape, and saturated catchments have greatly restricted farming activities; significant soil erosion has also been reported. Many catchments remain very vulnerable to relatively modest further rainfall. November has tested the resilience of existing flood alleviation strategies and sharpened the debate concerning the likely frequency of similar flood events in the future.

## Rainfall

November was a mild month but remarkable for the frequency of vigorous frontal systems which assailed much of the UK. Notable rainfall accumulations were commonplace and numerous local rainfall records have been established. Linton-on-Ouse (North Yorkshire) reported 154.8 mm over the 10 days beginning on the $29^{\text {th }}$ October - a period over which, nationally, the rainfall was equivalent to that normally registered over about six weeks. Thereafter, the speed of passage of the frontal systems helped to moderate storm totals somewhat. Nonetheless, apart from a few coastal locations in Scotland, November rainfall totals were above average, generally by a very wide margin. A large swathe of central and southern England again exceeded twice the monthly average. Northern Ireland had its wettest November since 1982 (boosted, locally, by a 48-hr total of 167 mm at Silent Valley on the 5-7th) whilst E\&W reported its $2^{\text {nd }}$ wettest November in the last 50 years. However, the autumn (Sept-Nov) totals are conspicuously more outstanding; only Nov 1929 - Jan 1930 has produced a higher 3-month rainfall total in the last 200 years. Rainfall accumulations over the period since mid-September are truly exceptional corresponding to over $60 \%$ of the annual average rainfall in many areas from the Pennines to Kent (reaching around 75\% in parts of Sussex and Kent). Numerous local rainfall records have been established and with heavy rainfall continuing into December, 90-100 day totals for large parts of England and Wales may well be without recorded precedent.

## Flows

Exceptional rainfall on the $29^{\text {th }}$ October (many areas received $>35 \mathrm{~mm}$ ) triggered significant flooding in catchments throughout much of the country. By early November, the severe but spatially restricted flooding of early October (in the South-East) had extended, initially to Yorkshire and then to many western catchments (the Severn Basin especially), parts of northern Britain and NI. Provisional data indicate that existing maximum flows were superseded on, for example, the Whiteadder, and the Annacloy in NI (on the 7/8th). Many rivers in E\&W reported peak flows with return periods in the 5-20 year range. Recessions ensued but with catchments saturated, surface storage exhausted, and watercourses running full, even modest additional rainfall was certain to bring further
inundation. Overall, the November flooding was most notable for its spatial extent and duration (embracing multiple flood events in many catchments) though some peak flows were outstanding (e.g. the Trent at Colwick registered its highest flow in a record from 1958). For around two-thirds of the index stations in E\&W, November runoff totals were unprecedented (including the Lee in a 118- year record), more notably, flows were unprecedented for any month at about a sixth of the sites. Extra-ordinary rates of aquifer recharge (see below) added a further dimension in mid-November as springfed streams were in high spate (e.g. the Meon and Lavant in Sussex) and groundwater flooding was reported from some localities (e.g. Hambledon, Hants). Hydrometric personnel have been extremely hard-pressed and final flow figures are awaited in some areas. Nonetheless, it appears that in the last 50 years only the flooding of March 1947 (when snowmelt over frozen ground produced remarkable runoff rates) and, possibly, that experienced in December 1965 were of comparable, or greater, magnitude when considered in a national perspective. The eclipsing of some of the November peaks during December (e.g. on the Thames) signalled an additional phase in an event whose full significance awaits verification of peak flows, their analysis in a full historical context - and the termination of the flooding.

## Groundwater

Following the rapid elimination of soil moisture deficits in October, infiltration over the last 8 weeks has been remarkable. Effective rainfall totals for November were more than four times the monthly average throughout many eastern aquifer units; records maintained by the Environment Agency (Thames) confirm the recharge in some eastern outcrops to be the heaviest for the autumn in a series from 1920. Over large areas infiltration totals already exceed the full winter average. Correspondingly, recoveries in groundwater levels have been very steep (in responsive major and minor aquifers alike). At West Woodyates the water-table rose 25 metres in 18 days (to the $10 / 11$ ) and nearly 15 metres in 23 days (to the $19^{\text {th }}$ ) at Little Bucket. By the $8^{\text {th }}$, Chilgrove was overflowing having risen 30 metres since early October. Rises in the Carboniferous limestone (Alstonfield) were even more spectacular and, entering the winter, overall groundwater resources were at historically high levels.

## Rainfall accumulation maps

For many parts of southern and eastern Britain rainfall totals for September, October and November were each notably high (approaching or exceeding twice the average). A relatively dry September in much of the Highlands was a moderating factor in Scotland but nonetheless the autumn rainfall for the UK as a whole is the highest on record, in a series from 1900.

## River flow . . . River flow

## River flows - Novemb0er 2000

*Comparisons based on percentage flows alone can be misleading. A given percentage flow can represent extreme drought conditions in permeable catchments where flow patterns are relatively stable but be well within the normal range in impermeable catchments where the natural variation in flows is much greater. Note: the period of record on which these percentages are based varies from station to station.

## River flow . . . River flow

## Monthly river flow hydrographs

The river flow hydrographs show the monthly mean flow (bold trace), the long term average monthly flow (dotted trace) and the maximum and minimum flow prior to 1997 (shown by the shaded areas). Monthly flows falling outside the maximum/minimum range are indicated where the bold trace enters the shaded areas.

## River flow . . . River flow

## Groundwater

 Groundwater

Groundwater levels normally rise and fall with the seasons, reaching a peak in the spring following replenishment through the winter (when evaporation losses are low and soil moist). They decline through the summer and early autumn. This seasonal variation is much reduced when the aquifer is confined below overlying impermeable strata. The monthly max., min. and mean levels are displayed in a similar style to the river flow hydrographs. Note that most groundwater levels are not measured continuously - the latest recorded levels are listed overleaf.

Note. Due to the impact of abstraction on groundwater levels at The Holt borehole, it has been replaced as an index site by the Stonor Park well.

## Groundwater . . . Groundwater

## Groundwater levels - November 2000

The rankings are based on a comparison between the average level in the featured month (but often only single readings are available) and the average level in each corresponding month on record. They need to be interpreted with caution especially when groundwater levels are changing rapidly or when comparing wells with very different periods of record. Rankings may be omitted where they are considered misleading.

## National Hydrological Monitoring Programme

The National Hydrological Monitoring Programme was instigated in 1988 and is undertaken jointly by the Centre for Ecology and Hydrology, Wallingford (formerly the Institute of Hydrology - IH) and the British Geological Survey (BGS). Financial support for the production of the monthly Hydrological Summaries is provided by the Department of the Environment, Transport and the Regions, the Environment Agency (EA), the Scottish Environment Protection Agency (SEPA), the Rivers Agency (RA) in Northern Ireland, and the Office of Water Services (OFWAT).

## Data Sources

River flow and groundwater level data are provided by the regional divisions of the EA (England and Wales) and SEPA (Scotland), data for Northern Ireland are provided by the Rivers Agency and the Department of the Environment (NI). In all cases the data are subject to revision following validation (flood and drought data in particular may be subject to significant revision).

Reservoir level information is provided by the Water Service Companies, the EA, the West of Scotland and East of Scotland Water Authorities, and the Northern Ireland Water Service.

The National River Flow Archive (maintained by CEH Wallingford) and the National Groundwater Level Archive (maintained by BGS) provide the historical perspective within which to examine contemporary hydrological conditions.

## Rainfall

Most rainfall data are provided by The Met. Office (address opposite). To allow better spatial differentiation the rainfall data for Britain are presented for the regional divisions of the precursor organisations of the EA and SEPA. Following the discontinuation of The Met. Office's CARP system in July 1998, the areal rainfall figures have been derived using several procedures, including initial estimates based on MORECS*. Recent figures have been produced by The Met. Office, National Climate Information Centre (NCIC), using a technique similar to CARP. An initiative is underway with The Met. Office to provide more accurate areal figures and, since October 1999, to include more raingauges in the analysis. A significant number of additional monthly rainfall totals are currently being provided by the Environment Agencies; over the coming months further monthly
raingauge totals will be included for selected regions. Until the access to these additional data has stabilised the regional figures (and the return periods associated with them) should be regarded as a guide only.
*MORECS is the generic name for the Meteorological Office services involving the routine calculation of evaporation and soil moisture throughout Great Britain.

The National Hydrological Monitoring Programme depends on the active cooperation of many data suppliers. This cooperation is gratefully acknowledged; the Hydrological Summaries for the autumn of 2000, in particular, stand as a testimony to the assistance provided by many hydrometric personnel working in exceptionally challenging circumstances.

## Subscription

Subscription to the Hydrological Summaries costs $£ 48$ per year. Orders should be addressed to:

Hydrological Summaries

[^0]:    The monthly rainfall figures* are copyright of The Met. Office and may not be passed on to any unauthorised person or organisation. All monthly totals since December 1998 are provisional (see page 12). The return period estimates are based on tables provided by the Meteorological Office (see Tabony, R.C., 1977, The variability of long duration rainfall over Great Britain, Scientific Paper No. 37) and relate to the specified span of months only (return periods may be up to an order of magnitude less if $n$-month periods beginning in any month are considered); RP estimates for Northern Ireland are based on the tables for north-west England. The tables reflect rainfall over the period 1911-70 and assume a stable climate. Artifacts in the England \& Wales and Scotland rainfall series can exaggerate the relative wetness of the recent past. "See page 12 .

[^1]:    Details of the individual reservoirs in each of the groupings listed above are available on request. The featured reservoirs may not be representative of the storage conditions across each region; this can be particularly important during droughts. The minimum storage figures relate to the 1988-2000 period only (except for West of Scotland where data commence in 1994). In some gravity-fed reservoirs (e.g. Clywedog) stocks are kept below capacity during the winter to provide scope for flood attenuation purposes.
