# Hydrological summary for the United Kingdom <br> <br> General 

 <br> <br> General}

Most of the UK enjoyed a mild and generally sunny January but rainfall patterns displayed marked regional contrasts. Precipitation totals were well above average throughout much of Scotland but parts of the English lowlands were exceptionally dry. Despite the limited rainfall, overall reservoir contents remain very healthy; significant recoveries were reported for a few lowland pumped storage reservoirs where high pesticide concentrations in the rivers greatly restricted infill during December. The limited lowland rainfall resulted in only modest infiltration in almost all aquifer outcrop areas. Nonetheless, most groundwater levels are currently around the seasonal average; the lowest levels are in the east where late winter/early spring rainfall would be especially beneficial.

## Rainfall

Vigorous frontal systems - particularly during the first fortnight and at the end of the month - brought gales and abundant rainfall to large parts of Northern Britain, the Scottish Highlands especially. Notable storm rainfall totals were associated with a very slow-moving depression on the $10-12^{\text {th }}$ (e.g. 155 mm in 48 hrs at Capel Curig in north Wales and 54.6 mm in 24 hrs at Brampton, Cumbria). Anticyclonic conditions dominated southern and eastern Britain during January and the contrasting regional synoptic patterns are closely reflected in the precipitation totals. Above average totals were largely restricted to the mountains of north Wales, the Lake District and, particularly, the Scottish Highlands where a few raingauges recorded more than twice the January average. In central and southern England a few notably dry localities (e.g. in the Midlands and along the south coast) registered less than $20 \%$. Northern Ireland was dry also, reporting its second lowest January rainfall since 1987. A broad accentuation in the north-west/south-east rainfall gradient across the UK (a familiar feature of the recent past) is again evident over the last three months. The Nov-Jan period was (provisionally) the fourth wettest for Scotland in a series from 1869 whilst large parts of the Anglian, Thames and Southern regions have recorded $<80 \%$ of average rainfall. Considerably more regional coherence typifies rainfall accumulations in the 12 month (Feb-Jan) timespan, most regions - western Scotland aside - have recorded rainfall well within the normal range, with relatively low rainfall totals being confined to southern England.

## River flows

Entering 2000, catchments throughout the UK were saturated and vulnerable to further significant rainfall. Following widespread late-December flooding further floodplain inundations occurred in Scotland, particularly around the $6 / 7^{\text {th }}$ January - snowmelt was a contributory factor in many catchments. In northern England notable spates were triggered by the protracted rainfall over the $10-12^{\text {th }}$; flooding was significant in north Wales and in northern England the Eden exceeded bankfull at Carlisle and the South Tyne inundated parts of Haltwhistle. By mid-month, steep recessions characterised most rivers. These were reversed
over the final week in northern Britain but continued in the south where, entering February, flows were seasonally depressed in some impermeable catchments.
Monthly runoff totals displayed very wide regional and local variations. Near average totals characterised many spring-fed rivers in the English lowlands (reflecting a high groundwater component following heavy December recharge) whilst flows in impermeable catchments were generally low, below half the monthly averages in some rivers (e.g. the Wallington and Medway). By contrast, runoff totals for many Scottish catchments ranked amongst the highest quartile. Over the Nov-Jan period, runoff totals are outstanding for some Scottish catchments (e.g. the Clyde). In a few low-lying eastern catchments (e.g. the Whiteadder) corresponding totals are below average - a pattern widely repeated in the English lowlands.

## Groundwater

Soils remained wet throughout January - at month-end appreciable soil moisture deficits were confined to a small area inland from the Wash. But the rainfall distribution in January was very unfavourable in groundwater terms - rainfall to the Chalk outcrops being typically in the $30-40 \%$ range. Consequently, infiltration was very modest and the exceptionally brisk rises reported for many index wells and boreholes in December were reversed or greatly moderated in January. Notwithstanding this erratic behaviour, levels in the Chalk are generally close to the late-winter average across most of the outcrop. An exception is in Northern Ireland where low rainfall together with the unusual responsiveness of the Killyglen well (to which the overlying gravels is a contributory factor), resulted in a very steep decline from the December peak. Levels in the limestone aquifers declined briskly over the latter half of January but remain close to the January average. Moderate declines also characterised the more responsive Permo-Triassic sandstones outcrops - with sluggish recoveries continuing in the slowest responding units. Generally, levels remain healthy in the more westerly outcrops but low in the east.

Substantially above average

Above average

Normal range

Below average

Substantially below average

Exceptionally low rainfall

November 1999 - January 2000

February 1999 - January 2000

## Rainfall accumulation maps

The preferred paths of most rain-bearing frontal systems is reflected in the November - January rainfall figures. In this timeframe, Scotland was again notably wet - concluding a ten-year sequence when the November - January precipitation has been more than $15 \%$ greater than average for the preceding record. Over the 12 -month timespan, the February January rainfall total for the UK is the third in succession to be well above the 1961-90 average.

## River flows - January 2000

*Comparisons based on percentage flows alone can be misleading. A given percentage flow can represent extreme drought conditions in permeable catchments where flow patterns are relatively stable but be well within the normal range in impermeable catchments where the natural variation in flows is much greater.

## River flow

## River flow

## Monthly river flow hydrographs

The river flow hydrographs show the monthly mean flow (bold trace), the long term average monthly flow (dotted trace) and the maximum and minimum flow prior to 1997 (shown by the shaded areas). Monthly flows falling outside the maximum/minimum range are indicated where the bold trace enters the shaded areas.

## River flow . . . River flow

## Groundwater . . . Groundwater

## What is groundwater?

Groundwater is stored in the natural water bearing rock strata (or aquifers) which are found mostly in southern and eastern England (see page 11) where groundwater is the major water supply source. Groundwater levels normally rise and fall with the seasons, reaching a peak in the spring following replenishment through the winter (when evaporation losses are low and soil moist). They decline through the summer and early autumn. This seasonal variation is much reduced when the aquifer is confined below overlying impermeable strata. The monthly max., min. and mean levels are displayed in a similar style to the river flow hydrographs, note that most groundwater levels are not measured continuously - the latest recorded levels are listed overleaf.

## Groundwater . . . Groundwater

## Groundwater levels - January 2000

The rankings are normally based on a comparison of current levels (usually a single reading in a month) with the average level in each corresponding month on record. They need to be interpreted with caution especially when groundwater levels are changing rapidly or when comparing wells with very different periods of record. Rankings may be omitted where they are considered misleading.

# National Hydrological Monitoring Programme 

The National Hydrological Monitoring Programme was instigated in 1988 and is undertaken jointly by the Institute of Hydrology (IH) and the British Geological Survey (BGS). Financial support for the production of the monthly Hydrological Summaries is provided by the Department of the Environment, Transport and the Regions, the Environment Agency (EA), the Scottish Environment Protection Agency (SEPA), the Rivers Agency (RA) in Northern Ireland, and the Office of Water Services (OFWAT).

## Data Sources

River flow and groundwater level data are provided by the regional divisions of the EA (England and Wales) and SEPA (Scotland), data for Northern Ireland are provided by the Rivers Agency and the Department of the Environment (NI). In all cases the data are subject to revision following validation (flood and drought data in particular may be subject to significant revision).

Reservoir level information is provided by the Water Service Companies, the EA, the West of Scotland and East of Scotland Water Authorities, and the Northern Ireland Water Service.

The National River Flow Archive (maintained by IH ) and the National Groundwater Level Archive (maintained by BGS) provide the historical perspective within which to examine contemporary hydrological conditions.

## Rainfall

Most rainfall data are provided by The Met. Office (address opposite). To allow better spatial differentiation the rainfall data for Britain are presented for the regional divisions of the precursor organisations of the EA and SEPA. Since the discontinuation of The Met. Office's CARP system in July 1998, rainfall figures have been provided by differing methods. Initial rainfall estimates for Scotland and the Scottish regions were derived by IH in collaboration with SEPA. In England and Wales, between July 1998 and May 1999, provisional rainfall figures derive from MORECS*. Beginning with the June 1999 report, provisional rainfall figures for England and Wales, the EA regions and Northern Ireland (from September 1999) have been produced by The Met. Office, National Climate Information Centre (NCIC), using a technique similar to CARP. An initiative is underway
with The Met. Office to provide more accurate areal figures and, since October 1999, to include more raingauges in the analysis. A significant number of additional monthly rainfall totals are currently being provided by SEPA; over the coming months further monthly raingauge totals will be included for selected EA regions. Until the access to these additional data has stabilised the regional figures (and the return periods associated with them) should be regarded as a guide only.
*MORECS is the generic name for the Meteorological Office services involving the routine calculation of evaporation and soil moisture throughout Great Britain.

[^0]:    The monthly rainfall figures* are copyright of The Met. Office and may not be passed on to any unauthorised person or organisation. All monthly totals since July 1998 are provisional (see page 12). Recent monthly rainfall figures for the Scottish regions have been compiled using data provided by the Scottish Environment Protection Agency. The return period estimates are based on tables provided by the Meteorological Office (see Tabony, R.C., 1977, The variability of long duration rainfall over Great Britain, Scientific Paper No. 37) and relate to the specified span of months only (return periods may be up to an order of magnitude less if $n$-month periods beginning in any month are considered); RP estimates for Northern Ireland are based on the tables for north-west England. The tables reflect rainfall over the period 1911-70 and assume a stable climate. Artifacts in the England \& Wales and Scotland rainfall series can exaggerate the relative wetness of the recent past. *See page 12 .

[^1]:    Details of the individual reservoirs in each of the groupings listed above are available on request. The featured reservoirs may not be
    representative of the storage conditions across each region; this can be particularly important during droughts. The minimum storage figures relate to the 1988-2000 period only (except for West of Scotland where data commence in 1994). In some gravity-fed reservoirs (e.g. Clywedog) stocks are kept below capacity during the winter to provide scope for flood attenuation purposes.
