# Hydrological summary for the United Kingdom <br> <br> General 

 <br> <br> General}

Overall, November was another mild month with near average rainfall for the UK as a whole - but regional variations were large. These are reflected in differences in the seasonal recoveries of runoff and aquifer recharge rates, but November river flows and groundwater levels were generally well within the normal range. The late November/early December rainfall has been particularly welcome in a few eastern aquifer outcrop areas where the seasonal upturn in groundwater levels is still awaited. Stocks declined modestly in a few reservoirs but most reported an appreciable increase through November; overall stocks for England and Wales remain significantly above average for the beginning of winter.

## Rainfall

November witnessed a variety of synoptic patterns allowing airmasses to cross the British Isles from many directions. Overall, westerly airflows predominated but many of the rain-bearing frontal systems followed tracks relatively remote from the English lowlands. Much of the UK experienced a dry, and cold, interlude in mid-November bracketed by wet conditions (in northern Britain especially) - vigorous depressions caused structural damage, substantial transport disruption and flooding during these very unsettled episodes. On the $5^{\text {th }}$, a slowmoving depression produced notable storm totals in parts of north-western Britain - reaching $90-100 \mathrm{~mm}$ in west Cumbria (e.g. at Summergrove and Ennerdale), triggering significant flooding. Storm totals exceeding 40 mm were also common on the $28^{\text {th }}$ heralding a notably wet spell (East Kilbride reported 62 mm on the $28^{\text {th }}$ and 52 mm in ten hours on the $30^{\text {th }}$ ). November rainfall totals were well above average in large parts of Scotland, particularly so in many Highland catchments. By contrast, monthly totals were only around half the average in the east Midlands and below $35 \%$ in a few southern coastal districts (e.g. Sussex). For England and Wales, only in 1995 has a similarly dry Oct/Nov been experienced since 1988. Nonetheless, a very wet September ensured that autumn (Sept-Nov) rainfall totals were well within the normal range in all regions - this is generally true of accumulations over 6 and 12 months also.

## River Flows

Contrary to the normal seasonal trend, runoff from most catchments in southern Britain declined relative to the October totals. Modest flows were also widely experienced in mid-November across Scotland and Northern Ireland. However, many Scottish catchments away from the eastern coastal strip, reported well above average runoff for November - largely a consequence of notably high flows in the first and last weeks; peak flows were the highest of the year in many areas. Local flooding was common around the $5^{\text {th }}$ throughout northern Britain, and extending to the Midlands. It was particularly severe in West Cumbria where low-lying parts of Whitehaven and Egremont were inundated - levels in the River Ehen (at

Braystones) exceeded the previous maximum in a record from 1976. Flooding was more widespread on the $28^{\text {th }}$ heralding a cluster of spates; some localities were subject to several flood episodes (e.g. Port Glasgow). The Yarrow Water (at Gordon Arms) registered its second highest flow in a 33-year record. Transport disruption was substantial and widespread, exacerbated in Scotland by landslides (e.g. at Labert, blocking the main rail link to the north from Glasgow). Localised flooding also occurred in rivers draining to Lough Foyle in Northern Ireland. By contrast, spates in the English lowland rivers were very modest and November runoff totals were appreciably below average in most catchments, notably so in the SouthEast where, in some catchments, the faltering seasonal recovery is reflected in autumn runoff totals of below $50 \%$. Elsewhere, however, most are well within the normal range, and healthy over the December 1998 November 1999 timespan.

## Groundwater

The regional distribution of the November rainfall, combined with continuing soil moisture deficits in the east (East Anglia especially), resulted in the seasonal recovery being delayed or, to the west, gaining little momentum in the major aquifers. The limited lateautumn infiltration is of most significance in parts of the eastern Chalk - particularly in a zone from the North Downs to Cambridgeshire - and in a few PermoTriassic sandstones outcrops where the 1999 recession has left groundwater levels appreciably below average. Generally however, levels throughout the Chalk and most limestone outcrops remain close to the monthly average, as they have since the early spring. The Permo-Triassic sandstones, where response times and the impact of abstractions tend to be more influential, present a far less coherent picture. Notably high groundwater levels characterise parts of the SouthWest and north Wales but levels remain depressed in some slow-responding eastern outcrops, particularly where exceptionally low levels were experienced towards the end of the 1995-97 drought.

## Rainfall accumulation maps

Autumn (September-November) rainfall has been well within the normal range in all regions. Similarly, for the last twelve months, once again, the December-November accumulation for Scotland is significantly above average. In this timeframe, Scottish rainfall over the last 20 years exceeds the preceding average by around $13 \%$ (a minor proportion of which is attributable to artifacts in the series which began in 1869).

## River flow. . . River flow. . .

## River flows - November | 999

*Comparisons based on percentage flows alone can be misleading. A given percentage flow can represent extreme drought conditions in permeable catchments where flow patterns are relatively stable but be well within the normal range in impermeable catchments where the natural variation in flows is much greater.

## Monthly river flow hydrographs

The river flow hydrographs show the monthly mean flow (bold trace), the long term average monthly flow (dotted trace) and the maximum and minimum flow prior to 1996 (shown by the shaded areas). Monthly flows falling outside the maximum/minimum range are indicated where the bold trace enters the shaded areas.

## Groundwater . . . Groundwater

## What is groundwater?

Groundwater is stored in the natural water bearing rock strata (or aquifers) which are found mostly in southern and eastern England (see page 11) where groundwater is the major water supply source. Groundwater levels normally rise and fall with the seasons, reaching a peak in the spring following replenishment through the winter (when evaporation losses are low and soil moist). They decline through the summer and early autumn. This seasonal variation is much reduced when the aquifer is confined below overlying impermeable strata. The monthly max., min. and mean levels are displayed in a similar style to the river flow hydrographs, note that most groundwater levels are not measured continuously - the latest recorded levels are listed overleaf.

## Groundwater. . . Groundwater

## Groundwater levels - November I 999

The rankings are normally based on a comparison of current levels (usually a single reading in a month) with the average level in each corresponding month on record. They need to be interpreted with caution especially when groundwater levels are changing rapidly or when comparing wells with very different periods of record. Rankings may be omitted where they are considered misleading.

## Location map . . . Location map

# National Hydrological <br> Monitoring Programme 

The National Hydrological Monitoring Programme was instigated in 1988 and is undertaken jointly by the Institute of Hydrology (IH) and the British Geological Survey (BGS). Financial support for the production of the monthly Hydrological Summaries is provided by the Department of the Environment, Transport and the Regions, the Environment Agency (EA), the Scottish Environment Protection Agency (SEPA), the Rivers Agency (RA) in Northern Ireland, and the Office of Water Services (OFWAT).

## Data Sources

River flow and groundwater level data are provided by the regional divisions of the EA (England and Wales) and SEPA (Scotland), data for Northern Ireland are provided by the Rivers Agency and the Department of the Environment (NI). In all cases the data are subject to revision following validation (flood and drought data in particular may be subject to significant revision).

Reservoir level information is provided by the Water Service Companies, the EA, the West of Scotland and East of Scotland Water Authorities, and the Northern Ireland Water Service.

The National River Flow Archive (maintained by IH) and the National Groundwater Level Archive (maintained by BGS) provide the historical perspective within which to examine contemporary hydrological conditions.

## Rainfall

Most rainfall data are provided by The Met. Office (address opposite). To allow better spatial differentiation the rainfall data for Britain are presented for the regional divisions of the precursor organisations of the EA and SEPA. Since the discontinuation of The Met. Office's CARP system in July 1998, rainfall figures have been provided by differing methods. Initial rainfall estimates for Scotland and the Scottish regions were derived by IH in collaboration with SEPA. In England and Wales, between July 1998 and May 1999, provisional rainfall figures derive from MORECS*. Beginning with the June 1999 report, provisional rainfall figures for England and Wales, the EA regions and Northern Ireland (from January 1999) have been derived by the National Climate Information Centre (NCIC), formerly the UK Climate

Studies Group, at The Met. Office. However, readers should note that the MORECS estimates have not been updated since July 1998. Negotiations are continuing with The Met. Office to provide more accurate areal figures and as a result, from October 1999, the rainfall estimates for the Scottish regions are derived by NCIC in a pilot collaboration with IH and SEPA. Until the negotiations are concluded the regional rainfall figures (and the return periods associated with them) should be regarded as a guide only.
*MORECS is the generic name for the Meteorological Office services involving the routine calculation of evaporation and soil moisture throughout Great Britain.

[^0]:    Details of the individual reservoirs in each of the groupings listed above are available on request. The featured reservoirs may not be representative of the storage conditions across each region; this can be particularly important during droughts. The minimum storage figures relate to the $1988-1999$ period only (except for West of Scotland where data commence in 1994). In some gravity-fed reservoirs (e.g. Clywedog) stocks are kept below
