# Hydrological summary for Great Britain 

## General

January was very unsettled and, in most regions, remarkably mild. Several reservoirs were drawndown to provide greater scope for flood mitigation and poor water quality restricted the replenishment of a few pumped storage reservoirs. Nonetheless, overall stocks remain exceptionally healthy - most reservoirs are very close to capacity. Weather conditions were also ideal for groundwater recharge and, by month-end, the overall resources outlook was very encouraging (moderated only by the precedent of 1995 when prospects deteriorated rapidly through an extremely dry spring).

## Rainfall

Weather patterns in January were dominated by a succession of westerly frontal systems; gales were common especially in northern Britain which experienced both blizzards and a significantly increased avalanche risk. On the $5 / 6^{\text {th }}, 24$-hour rainfall totals in excess of 100 mm were reported from Windermere and Dolydd (Wales). A complex low pressure system produced significant rainfall totals over a much wider area on the $15^{\text {th }}$-Brooksby in Leicestershire recorded 26 mm in four hours, Portland Bill (Dorset) 43 mm in 24 hours and Dolydd 69 mm in 15 hours. Generally however, January was notable for the frequency of storm events - with a very high number of 'wet' days in the South-East - rather than the magnitude of rainfall totals. Although a few raingauges in north-eastern Scotland registered only around half the January average, most regional totals were in the $120-150 \%$ range - adding to a cluster of recent wet Januarys; for Britain as a whole, seven of the fourteen wettest in a record from 1869 have occurred in the last fifteen years. Rainfall accumulations over a range of timespans are also generally above average; those for September-January being particularly important in water resources terms especially in parts of the English Lowlands where it was the wettest such period for over twenty years. A particularly wet phase can be traced back to November 1997 - for Britain, the last 15 months ranks, provisionally, alongside 1993/95 as the second wettest such sequence this century.

## River Flow

The well above average rainfall and saturated condition of most catchments resulted in spate conditions throughout January in most areas. Tidal flooding occurred early in the month (e.g. at Selsey) followed by significant fluvial flooding in northern Britain around the 6th - which was particularly severe in Cumbria; the peak flow on the Lune was (provisionally) the second highest in at least 20 years. The passage of a very active frontal system on the 15 th triggered floodplain inundations over an exceptionally wide area. Steep impermeable western catchments responded initially, along with some lowland clay catchments (e.g. in Berkshire) - in a few localities, for example Cranleigh near Guildford, local flooding was exacerbated
by partially blocked storm drains. In the third week, flood alerts applied to many rivers and further flooding occurred in the South-West (e.g. around the $20^{\text {th }}$ at Bedminster, Chew Magna and near Taunton) following up to 40 mm of rainfall over 24 hours. Generally however the speed of the frontal systems limited the duration of storms - and the corresponding rainfall amounts - helping to prevent major flooding; the return period of most peak flows was around the 3-5 year mark. Nonetheless, monthly runoff totals were amongst the highest on record in many catchments and rivers registering unprecedented January totals show a wide distribution - including the Soar (in a 28year record), the Lune ( 39 years) and the Kennet for which the (provisional) runoff was the highest for any month in a record from 1961. Runoff totals are also outstanding in the 12 -month timeframe especially in northern Britain where the Clyde established a new February-January maximum.

## Groundwater

With soils saturated and significant pulses of rainfall throughout the month, groundwater replenishment in January was heavy in almost all major aquifer units; in some eastern areas infiltration in January exceeded twice the monthly average. As importantly in resources terms, infiltration has continued, albeit unevenly, since mid-autumn and generally groundwater levels have been rising briskly since the early winter. Levels in the deeper wells to the north of London - which, in early January 1998 were the lowest on record (e.g. at The Holt and Redlands) - are rising steeply. January levels at Rockley and Chilgrove peaked close to long term maxima, the latter was close to becoming artesian late in the month - the third exceptionally high level in the last six years. Similarly late-January levels were very high in the Limestone aquifers. The position in the Permo-Triassic sandstones is less spatially coherent. Levels at Skirwith, Llanfair and Yew Tree Farm are the highest for almost four years but the benefit of the abundant infiltration over the winter is still awaited at a few very slow responding index sites.

The monthly rainfall figures* are copyright of the Met. Office and may not be passed on to any unauthorised person or organisation. Recent monthly rainfall figures for the Scottish regions have ben compiled using data provided by the Scottish Environment Protection Agency. The return period estimates are based on tables provided by the Meteorological Office (see Tabony, R.C., 1977, The variability of long duration rainfall over Great Britain, Scientific Paper No. 37) and relate to the specified span of months only, (return periods may be up to an order of magnitude less if $n$-month periods beginning in any month are considered). The tables reflect rainfall over the period 1911-70 and assume a stable climate. Artifacts in the England \& Wales and Scotland rainfall series can exaggerate the relative wetness of the recent past. *See page 12.

Very wet
average

November I 998 - January 1999

## Rainfall accumulation maps

Below average regional rainfall totals over the November-January period have been confined to north-eastern Britain. Accumulated totals in the 12 -month timeframe are especially notable: February-January totals are well above average in all regions and. for Britain as whole, provisional rainfall figures suggest that only 1992/93 has been wetter since 1927/28 (but 1994/95 was comparably as wet also).

## River flow . . . River flow

## River flows - January 1999

*Comparisons based on percentage flows alone can be misleading. A given percentage flow can represent extreme drought conditions in permeable catchments where flow patterns are relatively stable but be well within the normal range in impermeable catchments where the natural variation in flows is much greater.

## River flow . . . River flow .

## Monthly river flow hydrographs

The river flow hydrographs show the monthly mean flow (bold trace), the long term average monthly flow (dotted trace) and the maximum and minimum flow prior to 1993 (shown by the shaded areas). Monthly flows falling outside the maximum/ minimum range are indicated where the bold trace enters the shaded areas.

## Groundwater . . . Groundwater

## What is groundwater?

Groundwater is stored in the natural water bearing tock strata (or aquifers) which are found mostly in southern and eastern England (see page 11) where groundwater is the major water supply source. Groundwater levels normally rise and fall with the seasons, reaching a peak in the spring following replenishment through the winter (when evaporation losses are low and soil moist). They decline through the summer and early autumn. This seasonal variation is much reduced when the aquifer is confined below overlying impermeable strata. The monthly max., min. and mean levels are displayed in a similar style to the river flow hydrographs, note that most groundwater levels are not measured continuously - the latest recorded levels are listed overleaf.

## Groundwater . . . Groundwater

## Groundwater levels - January I 999

The rankings are based on a comparison of current levels (usually a single reading in a month) with the average level in each corresponding month on record. They need to be interpreted with caution especially when groundwater levels are changing rapidly or when comparing wells with very different periods of record.

## Location map . . . Location map

## Where the information comes from

The National Hydrological Monitoring Programme was instigated in 1988 and is undertaken jointly by the Institute of Hydrology (IH) and the British Geological Survey (BGS). Financial support for the production of the monthly Hydrological Summaries is provided by the Department of the Environment, Transport and the Regions, the Environment Agency (EA), the Scottish Environment Protection Agency (SEPA) and the Office of Water Services (OFWAT).

## River flow and groundwater levels

The National River Flow Archive (maintained by IH) and the National Groundwater Level Archive (maintained by BGS) provide the historical perspective within which to examine contemporary hydrological conditions.

River flow and groundwater level data are provided by the regional divisions of the EA (England and Wales) and SEPA (Scotland). In all cases the data are subject to revision following validation (flood and drought data in particular may be subject to significant revision).

## Reservoirs

Reservoir level information is provided by the Water Service Companies, the EA and, in Scotland, the West of Scotland and East of Scotland Water Authorities.

## Rainfall

Most rainfall data are provided by the Met Office. To allow better spatial differentiation the rainfall data are presented for the regional divisions of the precursor organisations of the EA and SEPA. The recent rainfall estimates for the Scottish regions are derived by IH in collaboration with the SEPA regions. In England and Wales the recent rainfall figures derive from MORECS. MORECS is the generic name for the Meteorological Office services involving the routine calculation of evaporation and soil moisture throughout Great Britain. The discontinuation of the CARP system used by the Met. Office to provide more definitive regional rainfall assessments means that the recent MORECS figures have not been updated. Negotiations are continuing with the Met. Office to provide more accurate areal figures. Until the negotiations are concluded the regional rainfall figures (and the return periods associated with them) should be regarded as a guide only.

[^0]:    Details of the individual reservoirs in each of the groupings listed above are available on request. The featured reservoirs may not be representative of the storage conditions across each area; this can be particularly important during droughts.
    The minimum storage figures relate to the 1988-1998 period only. In some gravity-fed reservoirs (eg. Clywedog) stocks are kept below capacity during the winter to provide scope for flood attenuation purposes.
