# Hydrollogical summary for Great Britain 

## General

April is often a pivotal month in relation to the water resources outlook. An exceptionally dry April in 1995 signalled the start of a drought which, in parts of England, was not terminated until last month - the wettest April on record for Britain as a whole, in a series from 1869. Overall reservoir stocks in early May were the highest since national monitoring began a decade ago. The remarkable April rainfall patterns culminated in exceptionally severe flooding in the south Midlands over Easter - the most damaging floods in the UK since the summer floods of 1968. From a groundwater perspective however, the April rainfall was decidedly beneficial - producing a very late surge of aquifer replenishment - leaving water-tables within the normal range in almost all areas.

## Rainfall

April was generally a dull, cool and remarkably wet month. Some central and southern districts reported only two dry days in the entire month as a sequence of frontal systems assailed Britain from various quarters. Notwithstanding below average rainfall in a few north-western areas, Scotland registered around twice the 1961-90 mean. In England some districts - mostly in the Midlands and the south - exceeded $300 \%$ of the April average. The provisional England and Wales total for April is the highest since 1818. On the 9 th, a frontal system aligned along a broad swathe from Gloucestershire to the Wash became very slow moving - many catchments received the equivalent of more than a months rainfall in under 10 hours. In many localities storm totals were in the $40-65 \mathrm{~mm}$ band and rain-day totals reached $70-80 \mathrm{~mm}$ at Pershore (Hereford and Worcester) and Althorpe Park (Northants). The last three months have been exceptionally wet in parts of western Scotland and the spring thus far has been the second wettest for over 50 years in E\&W. Regional rainfall totals in the 6 and 12 month timeframes are also well above average. Deficiencies can still be recognised over timespans of around three years - e.g. in the eastern Thames basin where they continue to be reflected in the groundwater levels (see opposite).

## River Flow

The recovery in flow rates during March (following notably low February flows) gathered momentum in April. Widespread minor spates occurred on the 3rd and, with catchments saturated, rivers were very susceptible to further significant rainfall. The storm on the 9th principally affected the mostly flat, impermeable and saturated clay vales of the Avon (Warwickshire) and Nene basins (and extending north towards the Soar basin). Rainfall intensities of $5-10 \mathrm{~mm}$ an hour for 6-10 hours were typical. A number of catchments in the region are particularly vulnerable to storms of this duration and substantial flooding was inevitable. In the event; flows exceeded previous maxima in most of the affected region. Oustanding flows were reported for the Avon and a number of tributaries (the Leam particularly); flood peaks
were remarkable on the Cherwell also. Initial estimates of return periods for the peaks exceed 50 years. Most gauging station records extend back only 30-40 years but a longer, albeit less reliable, perspective is provided by flood marks on bridges and buildings. These confirmed the exceptional magnitude of the Easter floods; at Evesham (on the Avon) levels exceeded the 1900 and 1848 peaks. Catchments establishing new maximum runoff totals showed a wide distribution from the Scottish Dee (at Park) to the Yscir in South Wales. The seasonally delayed recoveries were especially welcome in many eastern spring-fed streams; runoff in the Mimram was the the highest for two years, albeit still significantly below average.

## Groundwater

For much of April, soils were close to saturation - a rare circumstance in the English lowlands which created difficulties for farmers and growers but allowed much needed replenishment to eastern aquifers - at a time when groundwater level recessions are normally well established. In much of the Thames region, estimated percolation during April was 5-10 times the average; for some aquifer units it was the highest, for April, in records extending back over 75 years. In the Chalk, the March recessions in the west and south of the outcrop were reversed and, in parts of the east, very belated recoveries were triggered from an exceptionally low base. Overall groundwater resources in the Chalk are now close to the seasonal average. In the zone where water-tables were most depressed earlier in the year, recoveries have, as yet, been modest but levels at the Holt and Redlands boreholes have risen above those of last year and 1992 also. The Therfield well remains dry but the spring infiltration has yet to reach the deep water-table. A similar situation may be found in some of the very slow responding Permo-Triassic sandstones boreholes (e.g. Morris Dancers) but levels in most are well above 1996 and 1997 minima. Late April average levels in most of the more responses limestone outcrops were appreciably above average - notably so at Ampney Crucis.

The monthly rainfall figures are copyright of the Meteorological Office and may not be passed on to any unauthorised person or organisation. Recent monthly rainfall figures for the Scottish regions have ben compiled using data provided by the Scottish Environment Protection Agency. The return period estimates are based on tables provided by the Meteorological Office (see Tabony, R.C., 1977, The variability of long duration rainfall over Great Britain, Scientific Paper No. 37) and relate to the specified span of months only, (return periods may be up to an order of magnitude less if n-month periods beginning in any month are considered). The tables reflect rainfall over the period 1911-70 and assume a stable climate. Artifacts in the England \& Wales and Scotland rainfall series can exaggerate the relative wetness of the recent past.

## Rainfall accumulation maps

Much of Britain has been notably wet over both the last 6 and last 12 month periods. For England and Wales the MayApril period was the fourth wettest in the last 30 years and the November-April rainfall adds to a cluster of recent winter/ spring periods when rainfall totals are substantially different from the 1961-90 average.

## River flow . . . River flow . . .

## River flows - April 1998

Comparisons based on percentage flows alone can be misleading. A given percentage flow can represent extreme drought conditions in permeable catchments where flow patterns are relatively stable but be well within the normal range in impermeable catchments where the natural variation in flows is much greater.
Errata: The percentage river flows were correctly featured on the March 1998 map but erroneous colour codes were used for several of the station symbols (including those for the Yscir. Dee and Trent). A correct version of the map may be viewed on the Institute of Hydrology's Web Site (see back page) - navigate via Water Wateh.

## Monthly river flow hydrographs

The river flow hydrographs show the monthly mean flow (bold trace), the long term average monthly flow (dotted trace) and the maximum and minimum flow prior to 1992 (shown by the shaded areas). Monthly flows falling outside the maximum/ minimum range are indicated where the bold trace enters the shaded areas.

## Groundwater . . . Groundwater

## What is groundwater?

Groundwater is stored in the natural water bearing rock strata (or aquifers) which are found mostly in southern and eastern England (see page 11) where groundwater is the major water supply source. Groundwater levels normally rise and fall with the seasons, reaching a peak in the spring following replenishment through the winter (when evaporation losses are low and soil moist). They decline through the summer and early autumn. This seasonal variation is much reduced when the aquifer is confined below overlying impermeable strata. The monthly max., min. and mean levels are displayed in a similar style to the river flow hydrographs, note that most groundwater levels are not measured continuously - the latest recorded levels are listed overleaf.

## Groundwater . . . Groundwater

## Groundwater levels - April 1998

The rankings are based on a comparison of current levels (usually a single reading in a month) with the average level in each corresponding month on record. Caution needs to be exercised when interpreting the ranking, especially during periods of rapid changes in groundwater level. Rankings may be omitted where they are considered misleading.

## Location map . . . Location map

## Where the information comes from

The National Hydrological Monitoring Programme was instigated in 1988 and is undertaken jointly by the Institute of Hydrology (IH) and the British Geological Survey (BGS). Financial support for the production of the monthly Hydrological Summaries is provided by the Department of the Environment, Transport and the Regions, the Environment Agency (EA), the Scottish Environment Protection Agency (SEPA) and the Office of Water Services (OFWAT).

## River flow and groundwater levels

The National River Flow Archive (maintained by IH) and the National Groundwater Level Archive (maintained by BGS) provide the historical perspective within which to examine contemporary hydrological conditions.

River flow and groundwater level data are provided by the regional divisions of the EA (England and Wales) and SEPA (Scotland). In all cases the data are subject to revision following validation (flood and drought data in particular may be subject to significant revision).

## Reservoirs

Reservoir level information is provided by the Water Service Companies, the EA and, in Scotland, the West of Scotland and East of Scotland Water Authorities.

## Rainfall

Most rainfall data are provided by the Met Office. To allow better spatial differentiation the rainfall data are presented for the regional divisions of the precursor organisations of the EA and SEPA. The recent rainfall estimates for the Scottish regions are derived by IH in collaboration with the SEPA regions. In England and Wales the recent rainfall figures derive from MORECS. MORECS is the generic name for the Meteorological Office services involving the routine calculation of evaporation and soil moisture throughout Great Britain. The provisional regional rainfall figures are regularly updated using figures derived from a much denser rainguage network. Further details of Met. Office services can be obtained from:

The Meteorological Office
Sutton House
London Road
Bracknell
RG12 2SY.
Tel. 01344 856858; 01344854024.
The cooperation of all data suppliers is gratefully acknowledged.

## Subscription

Subscription to the Hydrological Summaries costs $£ 48$ per year. Orders should be addressed to:
Hydrological Summaries
Institute of Hydrology
Wallingford
Oxfordshire
OX10 8BB
Tel.: 01491838800
Fax: 01491692424

[^0]:    Details of the individual reservoirs in each of the groupings listed above are available on request. The featured reservoirs may not be representative of the storage conditions across each area; this can be particularly important during droughts.
    The minimum storage figures relate to the 1988-1997 period only. In some gravity-fed reservoirs (eg. Clywedog) stocks are kept below capacity during the winter to provide scope for flood alleviation.
