Abstract

Antibiotic resistance is a global health crisis linked to increased, and often unrestricted, antibiotic use in humans and animals. As one of the world's largest producers and consumers of antibiotics, China is witness to some of the most acute symptoms of this crisis. Antibiotics and antibiotic resistance genes (ARGs) are widely distributed in surface water, sewage treatment plant effluent, soils and animal wastes. The emergence and increased prevalence of ARGs in the clinic/hospitals, especially carbapenem-resistant gram negative bacteria, has raised the concern of public health officials. It is important to understand the current state of antibiotic use in China and its relationship to ARG prevalence and diversity in the environment. Here we review these relationships and their relevance to antimicrobial resistance (AMR) trends witnessed in the clinical setting. This review highlights the issues of enrichment and dissemination of ARGs in the environment, and also future needs in mitigating the spread of antibiotic resistance in the environment, particularly under the 'planetary health' perspective, i.e., the systems that sustain or threaten human health.

Keywords: Antibiotics; Antibiotic resistance gene; Environment; Clinical setting; Planetary health

63
64
65
66 **1. Introduction**
67

68 Antibiotics are used for treatment or prevention of bacterial infection. Nearly all
69 classes of antibiotic are based on the structure of antibiotics naturally found in
70 environmental microorganisms; with many of the antibiotics in widespread use being
71 synthetic derivatives of these natural structures (Demain 1999). Ever since penicillin
72 was introduced into medical therapy in 1942, hundreds of other antibiotics have been
73 isolated or synthesized for the treatment of human and animal infections. Antibiotics
74 played a significant role in the increase in life expectancy witnessed in the second-
75 half of the 20th century. Antibiotics transformed modern agriculture and livestock
76 industries, the latter of which used antibiotics for prophylaxis, meta-prophylaxis,
77 treatment for infection, and as a growth promoter to enhance feed efficiency in
78 healthy livestock (Sarmah et al. 2006).
79

80 The overuse and misuse of antibiotics stimulated the more rapid emergence of
81 antibiotic-resistant bacteria (ARB) and antibiotic resistant genes (ARGs), reducing
82 their therapeutic potential against human and animal pathogens (Wright 2010). World
83 Health Organization characterises antimicrobial resistance as a global public health
84 crisis that must be managed with the utmost urgency (WHO 2015).
85

86 The problem is particularly acute in China because of its antibiotic prescribing
87 practices, strong incentives for overprescribing, and the widespread use and misuse of
88 sub-therapeutic doses of antibiotics in agriculture (Yezli and Li 2012). Multidrug
89 resistance (MDR) bacteria, or ‘superbugs’, which are resistant to several different
90 antibiotics have been reported in China and antibiotic-resistant bacteria (ARB)
91 previously reported in China are now being seen to cause infections in other countries.
92 For example, Liu et al reported the emergence of the first plasmid-mediated colistin
93 resistance mechanism, *mcr-1*, in *Escherichia coli* from pigs, pork products, and
94 humans in 2015. At the time, it stated the belief that the gene is “currently confined to
95 China.” However, since then, scientists have found the MCR-1 gene in countries all
96 over the globe; additional colistin-resistance genes—MCR-2 and MCR-3—and

120
121
122 variants of those genes have also emerged and spread. The global AMR crisis has
123 only recently been met by a substantial increase in the number of studies focusing on
124 antibiotic resistance in the environment, aiming towards bridging the many
125 knowledge gaps (Singer et al. 2016). Here we aim to consolidate this recently-
126 acquired knowledge base on antibiotics and ARGs in the Chinese environment with
127 the intention of informing evidence-based strategies towards mitigating AMR in the
128 environment, a poorly acknowledged goal at the national and international level
129 (Singer 2017).

138 **2. Use and abuse of antibiotics in China**

139

140 China is one of the world's largest producers and consumers of antibiotics, widely
141 used for disease treatment in humans and livestock, and as prophylaxis and growth
142 promoters for the latter. A recent study showed that 92,700 tonnes of antibiotic
143 (inclusive of 36 antibiotics), were consumed in China in 2013; 48% of which were
144 consumed by humans, with the remaining by animals (Zhang et al. 2015c).
145 Approximately 46% of the antibiotics were ultimately released into rivers through
146 sewage effluent with the remaining to land through manure and sludge land spreading
147 (Zhang et al. 2015c). These usage estimates exceed usage in the UK and much of
148 northern Europe (normalised by the defined daily dose), by a factor of 6.
149
150
151
152
153
154
155

156 Approximately 50% of hospital outpatients in China are reported to use
157 antibiotics. Of these outpatients prescribed antibiotics, 74.0% were prescribed one
158 antibiotic, and 25.3% prescribed two or more antibiotics (Yin et al. 2013). The
159 prescription of antibiotics accounts for around half of all drugs prescribed by
160 hospitals, compared with just 10 percent in hospitals in high-income countries (RFA
161 2015). Cephalexin, amoxicillin, ofloxacin, tetracycline, and norfloxacin were the top
162 5 antibiotics used for human in 2013 in China (Zhang et al. 2015c). The excessive use
163 of antibiotics is particularly more problematic in lower-level hospitals and less
164 developed western China (Yin et al. 2013). About 75% of patients with seasonal
165 influenza are estimated to be prescribed antibiotics, and the rate of antibiotic

178
179
180 prescription for inpatients is 80% (Li 2014) which is much higher than the World
181 Health Organization recommended maximum level of 30%. This over prescription
182 may be because the drug sales occupy a significant part of hospital revenues (Currie et
183 al. 2014). Antibiotic prescription in a total of 48 primary health care facilities in China
184 showed that the most frequently prescribed antibiotics were cephalosporins (28%),
185 fluoroquinolones (15.7%), penicillins (13.9%), imidazoles (12.6%) and macrolides
186 (7.3%)(Wang et al. 2014c). The prescribing patterns of antibiotics are not effectively
187 controlled in China until the human medical system reform initiated by the Ministry
188 of Health of China in 2011 (Bao et al. 2015). Xiao et al. reported that the percentage
189 of hospitalised patients who were prescribed antibiotics fell by 10% in just one year,
190 from 68% in 2011 to 58% by the end of 2012. It also dropped 10% in outpatients in
191 the same time period, from 25% to 15% (Xiao and Li 2013). Sun et al reported a
192 significant reduction in overall inpatient antibiotic consumption in Chinese public
193 general tertiary hospitals after the interventions (Sun et al. 2015).

206 Modern animal husbandry often involves large and densely managed herds—
207 optimal conditions for the spread of infectious diseases. Antibiotic are routinely used
208 in an effort to manage this disease risk (Holman and Chenier 2015). Livestock
209 antibiotic use (52% of total antibiotic use) has been estimated at marginally higher
210 than human use (48%), as a percentage of antibiotic use in 2013 (subset of 36 highest
211 use antibiotics) (Zhang et al. 2015c). Consumption of veterinary antibiotics increased
212 from 46% in 2007 to 52% in 2013, totaling approximately 84,240 tonnes.
213 Amoxicillin, florfenicol, lincomycin, penicillin and enrofloxacin are the majority
214 veterinary antibiotics consumed at a rate >4000 tonnes in China (Van Boeckel et al.
215 2015; Zhang et al. 2015c). It has been estimated that the share of global antibiotic
216 consumption in food animal production for China will increase from 23% in 2010 to
217 30% in 2030 (Van Boeckel et al. 2015).
218
219
220
221
222
223
224
225
226

227 For therapeutic usage, animals are typically treated with antibiotics for a period of
228 3 to 7 days and then treated for another 3 or 4 days at prophylactic dosages (Wei and
229 Zhong 2011). Nontherapeutic use of antibiotics is the major contributor to usage
230 (Collignon and Voss 2015). Sub-therapeutic, in-feed antibiotics have been
231
232
233
234
235
236

237
238
239 investigated for livestock production since the late-1940's, only seven years after the
240 mass production of penicillin (Stokstad and Jukes 1950) and four years after the
241 discovery of chlortetracycline (Moore et al. 1946). Its use as a growth promoter
242 increased year on year, despite the recognition that such a practice selected for
243 resistance in the animals, farmers and veterinarians (Dibner and Richards 2005;
244 Marshall and Levy 2011).

245
246
247
248
249
250 The use of antibiotics in animal feeds has been regulated since 1989 in China
251 (Wang et al. 2008). Antibiotics may be added to feed at concentrations between 2.5
252 and 125 mg/kg of feed to improve growth for an undefined duration (weeks to
253 months), depending on the type and size of the animal and the type of antibiotic
254 (Marshall and Levy 2011). Therefore, the nontherapeutic use of antibiotics might
255 have played a larger role in the evolution and dissemination of multiple
256 antibiotic resistance than did therapeutic use since it usually involved long-term,
257 continuous exposure in a very large number of animals (McEwen and Fedorka-Cray
258 2002).

259
260
261
262
263
264
265
266
267 In general, antibiotics are poorly metabolised by humans and animals and as such
268 are excreted as the active parent chemical in the faeces and urine, entering the
269 environment through wastewater and manure. Antibiotic metabolites can also be
270 bioactive, and even if they are not bioactive, they can often be transformed back into
271 the parent compound or another bioactive substance. For example, the composition of
272 excreted sulfonamides (SAs) may contain approximately 9-30% parent compounds,
273 and between 5% and 60% acetylated conjugates. The metabolites, *N*4-
274 acetylsulfapyridine and *N*4-acetylsulfamethazine can be converted back to the parent
275 form (Bonvin et al. 2013; Garcia-Galan et al. 2012). Therefore, it is critical to know
276 about the environmental fate of antibiotics and their metabolites, which invariably
277 contribute to the increased prevalence and diversity of antibiotic resistance in China.

286

287 288 **3. Antibiotics residues in the environment**

289
290 Antibiotics enter into the environment via multiple pathways that include
291 effluents from the disposal of human waste, waste from agricultural food animal
292
293

296
297
298
299 production and aquaculture, direct application to some plants, industrial effluents
300 from pharmaceutical production, and agricultural run-off.
301

302 *3.1 Antibiotics in sewage treatment plants (STPs)* 303

304 Many studies have reported the detection of antibiotics in influent and effluent of
305 STPs in China (Chang et al. 2008; Chang et al. 2010; Gao et al. 2012; Gulkowska et
306 al. 2008; Hou et al. 2016; Hu et al. 2012; Jia et al. 2012; Leung et al. 2012; Li and
307 Zhang 2011; Li et al. 2009; Li et al. 2013a; Peng et al. 2006; Shao et al. 2009; Sun et
308 al. 2016; Wang et al. 2014a; Xu et al. 2015; Xu et al. 2007; Yan et al. 2014; Zhang et
309 al. 2013; Zhang et al. 2015b; Zhou et al. 2013b). The frequently reported compounds
310 include sulfadiazine, sulfamerazine, sulfamethazine, sulfamethoxazole, trimethoprim,
311 tetracycline, oxytetracycline, ciprofloxacin, enrofloxacin, norfloxacin, ofloxacin,
312 roxithromycin, and erythromycin-H₂O (Figure S1). The concentrations of these
313 antibiotics in both influents and effluents ranged from a few ng/L to tens of µg/L,
314 reflecting incomplete removal in conventional STPs. Antibiotic removal efficiencies
315 varied among different compounds and STPs. However, the reasons for the difference
316 in removal efficiencies among these STPs remains largely unknown. Different
317 physicochemical properties and daily loading of antibiotics, the types of treatment
318 processes and operational conditions of individual STPs, even the rainwater input, can
319 all affect the removal efficiencies. For example, **cephalexin**, as one of the most human
320 consumed antibiotics, the removal efficiencies ranged between 9 and 100%
321 (Gulkowska et al. 2008; Li and Zhang 2011; Li et al. 2009) in STPs of Hongkong. β-
322 lactams, like **cephalexin** and ampicillin, are easy to remove due to the
323 ready hydrolysis of the β-lactam ring and the ubiquity of β-lactamases in wastewater.
324 Despite the labile nature of some antibiotics, they can still be recovered from
325 wastewater, suggestive of their pseudopersistence (i.e., the rate of loss closely
326 matches the rate it enters the wastestream) (Leung et al. 2012). Another three highly
327 human consumed antibiotics, ofloxacin, norfloxacin and tetracycline were also widely
328 detected in STPs of China. The highest concentration of ofloxacin, norfloxacin and
329 tetracycline were found in the STP of Hongkong (7900 ng/L, 5430 ng/L and 1510
330 ng/L in influent and 7780 ng/L, 3700 ng/L and 1420 ng/L in effluent, respectively)
331

350
351
352
353
354

355
356
357
358 (Leung et al. 2012). Although their removal efficiencies vary among STPs, the
359 relatively higher removal rates of fluoroquinolones and tetracyclines (>70%) may
360 because these more hydrophobic antibiotics experience substantial removal from
361 wastewater as a result of partitioning to the solid (sludge) phase (Gulkowska et al.
362 2008; Li and Zhang 2011; Li et al. 2009; Peng et al. 2006; Xu et al. 2007). For many
363 sulfonamides, sorption to sludge was found to be negligible, therefore removal by
364 sorption to sludge is unlikely to be a primary removal mechanism for these
365 compounds. Limited removal of macrolides, like erythromycin-H₂O, were reported in
366 several STPs of China (Gulkowska et al. 2008; Leung et al. 2012; Li and Zhang
367 2011). It may because macrolides are mainly excreted in bile to faeces and the faecal
368 materials are digested during biological treatment, consequently increasing the
369 dissolved mass loads in effluent (Leung et al. 2012). The highest concentration of
370 ofloxacin (7900 ng/L) and norfloxacin (5430 ng/L) detected in influent of STP in
371 Hongkong was much higher than those reported in the USA (1000 ng/L) (Brown et al.
372 2006), Finland (960 ng/L) (Vieno et al. 2007) and Italy (980 ng/L) (Verlicchi et al.
373 2014). While the highest concentration of erythromycin-H₂O (4740 ng/L) was
374 relatively lower than the maximum concentration detected in influent from United
375 Kingdom (10025 ng/L) (Kasprzyk-Hordern et al. 2009). Sulfamethoxazole (SMX) is
376 one of the most frequently detected antibiotic compound in STP. The mean
377 concentration of SMX in STP influent (650 ng/L) in China was higher than that
378 reported in Korea (120 ng/L) (Behera et al. 2011), but comparable to that in Germany
379 (515 ng/L) (Rossmann et al. 2014) (Table S1).

400

401 There exist large differences in antibiotic emission from both human and
402 agricultural sources within each of the river basins of China (Zhang et al. 2015c).
403 Pearl River basin, located in south China, has the highest emission densities, followed
404 by the Haihe River basin, located in north China, and Taihu Lake and Qiantang River,
405 located in east China. The megacities of Guangzhou and Shenzhen are located in
406 Pearl River basin, while Beijing is located in the Haihe River basin. The east and west

China basins are separated by the "Hu Huanyong line" (i.e., a line that runs from Tengchong in the south to Aihui in the north), where the basins to the east of the line have 94% of the population of China, but only 43% of the land area. In general, the average emission densities of antibiotics followed the general population trends set by the "Hu Huanyong" line, with six times higher emission in the east and south, than in the west. This spatial trend is consistent with the antibiotic monitoring results for the surface water in China. Most studies reported the occurrence of antibiotics in the fast developing areas of China, such as Pearl River basin, however, little information is available in western China (Zhao et al. 2016).

471
472
A wide range of human and animal antibiotics have been detected in surface water and sediments of major Chinese rivers (Chen et al. 2013a; Chen and Zhou 2014; Jia et al. 2012; Li et al. 2014a; Luo et al. 2011; Tong et al. 2014; Xu et al. 2013; Xue et al. 2013; Yan et al. 2013; Yang et al. 2010; Yang et al. 2011; Zhang et al. 2012; Zheng et al. 2011; Zhou et al. 2011; Zhu et al. 2013a). The concentrations of antibiotics in surface water were found to range from below the detection limit (i.e., <10's ng/L) to the low $\mu\text{g/L}$ (Figure S2). Among them, sulfamethoxazole, oxytetracycline, ciprofloxacin, norfloxacin, ofloxacin, clarithromycin, and erythromycin- H_2O were frequently detected in the aqueous phase of rivers with concentrations up to a few $\mu\text{g/L}$. A wide range of antibiotics at the upper end of environmental concentrations are typical of rivers routinely receiving urban wastewater discharge and animal waste. The concentrations of antibiotics in sediments ranged from below detection limits (i.e., <10's ng/g) to the low $\mu\text{g/g}$ (Figure S3). Zhou et al. reported relatively low concentrations for sulfonamides (maximum 22 ng/g) and macrolides (maximum 67 ng/g), but high concentrations for fluoroquinolones (maximum 5770 ng/g) and tetracyclines (maximum 653 ng/g) in the sediments of the Yellow River, Hai River and Liao River in northern China (Zhou et al. 2011). Yang et al. reported similar results in the Pearl River in the southern China (Yang et al. 2010). Antibiotics, like fluoroquinolones and tetracyclines, strongly adsorb to suspended particles and sediment (Kümmerer 2009), indicating sediment could be a reservoir of antibiotics in the environment. Extremely high concentrations

473
474
475
476 of antibiotics were found in Haihe River, especially for sulfonamides, the highest
477 concentration of sulfachloropyridazine and sulfamethoxazole in tributaries of Haihe
478 River was 37000 ng/L and 3900 ng/L, respectively (Luo et al. 2011). The highest
479 concentrations of tetracyclines (oxytetracycline and tetracycline) and macrolides
480 (erythromycin-H₂O and roxithromycin) were all above 1500 ng/L level in tributaries
481 of Haihe River (Luo et al. 2011). Relatively high concentrations were also found in
482 the Pearl River (Yang et al. 2011), indicating the effects of a high population density.
483 Notwithstanding the high concentrations of antibiotics in the Haihe River,
484 environmental concentrations of antibiotics in surface waters in China are comparable
485 to or slightly higher than those reported in USA (Arikan et al. 2008; Kim and Carlson
486 2007), France (Tuc Dinh et al. 2011), Germany (Christian et al. 2003), Finland (Vieno
487 et al. 2007), Italy (Verlicchi et al. 2014) and Korea (Kim et al. 2007) (Table S1).

498 *3.3 Antibiotics in livestock farm wastes*

499
500 The great boom in the number of concentrated animal feeding operations
501 (CAFOs) for swine, poultry, and cattle production has driven demand for antibiotics.
502 Antibiotics use in animal husbandry ends up in the manure, due to the combination of
503 poor absorption and metabolism of the antibiotic in vivo. The total usage of
504 antibiotics for animals was 84240 tonnes in China (Zhang et al. 2015c), with a large
505 fraction of this held within the manure, which exceeds 2000 million tonnes for nearly
506 all animals in 2011 in China (Zhu and Ma 2014). Hence, livestock manure is a major
507 source of antibiotics, which enters through their application as fertilisers and soil
508 enhancers in agricultural fields and as diffuse pollution in stormwater runoff from
509 manure-amended fields.

510
511 Multiple classes of antibiotics have been recovered in the manure of swine,
512 chicken and cattle (Hou et al. 2015; Hu et al. 2008b; Hu et al. 2010; Huang et al.
513 2013b; Ji et al. 2012; Li et al. 2013c; Li et al. 2012; Pan et al. 2011; Qiao et al. 2012;
514 Zhang et al. 2015a; Zhao et al. 2010; Zhou et al. 2013a; Zhou et al. 2012; Zhou et al.
515 2013c). Fluoroquinolones (FQ), sulfonamides (SA) and tetracyclines (TC) were the
516 most frequently detected antibiotics and exhibited a broad concentration range (Figure
517

532
533
534 S4). Zhao et al. (2010), recorded the maximum concentration of enrofloxacin in
535 chicken litter ever reported in China, 1421 mg/kg. The authors also reported
536 the highest ever recorded concentration of norfloxacin in chicken manure, 225 mg/kg
537 (Zhao et al. 2010). Notably, the authors reported no appreciable sulfonamide
538 antibiotic concentrations (less than 10 mg/kg) in any animal dung. Zhang (2015),
539 reported oxytetracycline and chlortetracycline were the two most frequently recovered
540 antibiotics in animal manures and the highest concentration was 417 mg/kg in chicken
541 manure (Zhang et al. 2015a) and 764 mg/kg in swine manure (Pan et al. 2011),
542 respectively. In general, tetracyclines and fluoroquinolones were detected with higher
543 occurrence and higher concentrations than SAs; likely a result of the recalcitrance and
544 high partitioning of TC and FQ in manure. The highest concentrations of veterinary
545 antibiotics (enrofloxacin 1421 mg/kg and chlortetracycline 764 mg/kg) exceeded
546 those reported from Turkey (enrofloxacin 0.06 mg/kg and chlortetracycline
547 0.38mg/kg) (Karci and Balcioglu 2009), Austria (enrofloxacin 8.3 mg/kg and
548 chlortetracycline 46 mg/kg)(Martinez-Carballo et al. 2007), Germany
549 (chlortetracycline 50.8 mg/kg)(Holzel et al. 2010) and Canada (chlortetracycline 0.4
550 mg/kg)(Aust et al. 2008) (Table S1).

565 566 567 *3.4 Antibiotics in soil*

569 Antibiotics can be introduced into soil through irrigation with reclaimed water,
570 sludge and manure land application to crops or landfill, and the use of livestock
571 wastes as soil fertilisers. The concentration of antibiotics varies greatly across soils of
572 different origins, typically in the mid- to high- μg antibiotic per kg soil (Chen et al.
573 2014; Hou et al. 2015; Hu et al. 2010; Huang et al. 2013b; Ji et al. 2012; Li et al.
574 2014c; Qiao et al. 2012; Wang et al. 2014b; Wu et al. 2013; Wu et al. 2010; Zhou et
575 al. 2013a; Zhou et al. 2012; Zhou et al. 2013c) (Figure S5). Higher concentrations of
576 antibiotics were detected in soils adjacent to feedlots. For example, the maximum
577 chlortetracycline concentration (12.9 mg/kg) was found in soil near the effluent
578 discharge from a swine farm (Zhou et al. 2013a). Oxytetracycline was found with the
579 highest concentration of 4.24 mg/kg in an agricultural field adjacent to a swine farm

591
592
593
594 (Ji et al. 2012). Sulfadiazine and sulfamethoxazole from sulfonamide (SA) groups
595 were also found with the highest concentration of 2.45 mg/kg and 2.41mg/kg in soils
596 adjacent to a poultry farm (Ji et al. 2012). Antibiotic residues in organic vegetable
597 production are of particular concern since ‘organic’ sources of fertiliser (e.g., manure)
598 is often preferred over chemical fertilisers for building soil organic matter (Xie et al.
599 2016). Higher residues of FQs have been reported in an important vegetable-growing
600 region in Shandong province, China, with the maximum ciprofloxacin and ofloxacin
601 concentration of 0.652 mg/kg (Li et al. 2013b) and 0.288 mg/kg (Li et al. 2014c),
602 respectively. Accumulations of antibiotics were also found in soils irrigated with
603 either reclaimed water (Fang et al. 2015) or wastewater (Li et al. 2014c), but the
604 concentrations were lower as compared to soils sampled around feedlots. The
605 concentration of oxytetracycline in Chinese soils were similar to those in Turkey (20-
606 510 ng/g) (Karci and Balcioglu 2009), but lower than those in UK (322-1691 ng/g)
607 (Kay et al. 2004). Concentrations of sulfonamide in Chinese soils were comparable
608 with many other countries (Aust et al. 2008; Garcia-Galan et al. 2013; Ok et al. 2011;
609 Shelver et al. 2010; Watanabe et al. 2010) (Table S1).

620
621
622
623

624 **4. Antibiotic resistance in the environment and its potential health** 625 626 **impacts**

627
628 ARGs are a natural component of all environments (e.g., soil, water,
629 microbiomes). However, their increased prevalence as a result of human activities has
630 led to their characterisation as an emerging environmental contaminant (Pruden et al.
631 2006). The ARG burden in the environment has serious implications for human health
632 owing to the potential transfer of ARGs from environmental bacteria to human
633 pathogens, thereby impairing the efficacy of antibiotic treatment and compromising
634 public health. The frequent detected ARGs and their abundance levels in different
635 environmental media of China are listed in Table S2.
636
637
638
639
640
641
642

643 *4.1 ARGs in sewage treatment plants (STPs)*

644
645 STPs contribute to a reduction in the load of antibiotics and pathogenic
646
647
648
649

650
651
652
653 microorganisms into the receiving water body, however, this might not translate into a
654
655 significant reduction in overall risk, as the ratio of ARGs to total bacteria in STP
656
657 effluent can increase during treatment as could the frequency of recovering multi-drug
658
659 resistance (Czekalski et al. 2012). STPs are a highly favourable environment for the
660
661 selection of ARB or the horizontal gene transfer and propagation of ARGs because of
662
663 high microbial density, high nutrient content and sub-inhibitory concentrations of
664
665 antibiotics, biocides and metals.

665
666 Based on culture-dependent methods, 109 lactose-fermenting *Enterobacteriaceae*
667
668 (LFE) strains, important human pathogens, were isolated from the activated sludge of
669
670 the STP in Hong Kong and tetracycline-resistant LFE accounted for 32% of the total
671
672 109 LFE strains (Zhang et al. 2009a). Huang et al. investigated the antibiotic tolerance
673
674 of total heterotrophic bacteria and the concentration distribution of bacterial resistance
675
676 to six different antibiotics in the secondary effluent of the STP in Beijing. The
677
678 average percentages of chloramphenicol-, penicillin-, cephalothin-, ampicillin-,
679
680 rifampicin- tetracycline-resistant heterotrophic bacteria in the effluents were: 69%,
681
682 63%, 55%, 47%, 11% and 2.6% respectively. Above six ARB species were widely
683
684 distributed in four types of enterobacteria (*Aeromonas*, *Enterobacter*, *Escherichia* or
685
686 *Shigella*, and *Klebsiella*) from the secondary effluent (Huang et al. 2012).

685
686 DNA-based techniques, like PCR and quantitative real-time PCR, are
687
688 increasingly used to detect and quantify resistance genes in environmental samples in
689
690 addition to culture-based methods. Tetracycline (*tet*) and sulfonamide (*sul*) ARGs are
691
692 commonly detected because of the widespread use of the corresponding antibiotics
693
694 and their persistence in the environment. Mobile elements, such as integrons and
695
696 transposons, were also included in many studies because of their significant
697
698 contribution to the horizontal transfer of ARGs among bacterial species. The integrase
699
700 gene (*intI1*), belonging to class 1 integrons, was proposed to serve as a proxy of
701
702 pollution for resistant bacteria and other anthropogenic pollutants because of its rapid
703
704 response to diverse environmental pressures (Gillings et al. 2015). Among the
705
706 tetracycline resistance genes, three efflux pump genes (*tetA*, *tetC* and *tetG*), four
707
708 ribosomal protection proteins gene (*tetM*, *tetO*, *tetQ* and *tetW*) and one enzymatic

709
710
711
712 modification gene (*tetX*) seem to be the most common *tet* genes in the STPs of China
713 (Chen and Zhang 2013a; Du et al. 2014; Wen et al. 2016; Zhang et al. 2009a).
714 Sulfonamide-resistance genes: *sulI* and *sulII* were detected at high frequency across
715 China STPs. The ARG concentrations in STPs varied significantly across a range of
716 STPs; normalized by sample volumes, the concentrations of *tet* genes ranged from 10^2
717 to 10^{10} copies/mL (Chen and Zhang 2013a; Du et al. 2014; Li et al. 2016c; Pu et al.
718 2009; Wen et al. 2016; Zhang et al. 2009a). The maximum concentration of *tet* gene
719 in influent was found in a STP in Zhejiang province, in the east of China, $10^{11.17}$
720 copies/mL (Li et al. 2016c). The concentrations of ARGs in effluent samples (from
721 10^1 to 10^7 copies/mL) can decrease by 0.3 to 3 orders of magnitude (Chen and Zhang
722 2013a; Du et al. 2014; Li et al. 2016c; Mao et al. 2015; Pu et al. 2009; Wen et al.
723 2016; Zhang et al. 2009a). Compared to influent and effluent samples, sludge samples
724 had higher ARG abundance (from 10^7 to 10^{11} copies/g) and diversity (Chen and
725 Zhang 2013a; Du et al. 2014; Li et al. 2016c; Mao et al. 2015; Pu et al. 2009; Wen et
726 al. 2016; Zhang et al. 2009a; Zhang and Zhang 2011). *TetA* and *tetC*, with a broad
727 host range, were often detected with high concentrations (Huang et al. 2015a; Zhang
728 et al. 2009a). Horizontal co-transfer of *tetA* and class I integrons have been observed
729 among some species like *Aeromonas* in fish farms (Schmidt et al. 2001). A positive
730 correlation between efflux pump gene (*tetA*, *tetG*) and *intI1* was also observed in
731 some STPs, indicating the role of class I integrons in efflux pump genes (Chen and
732 Zhang 2013b; Huang et al. 2015b). In general, the abundance of *sul* was higher than
733 that of *tet*, likely because *sulI* is often associated with class I integrons. Based on the
734 normalized concentration of ARGs (relative to the total 16S rRNA gene copy
735 number), higher total loads of ARGs was observed in pharmaceutical STPs (10^{-4} - 10^0
736 copies/copy 16SrRNA gene) than in municipal STPs (10^{-9} - 10^{-1} copies/copy 16SrRNA
737 gene) (Huang et al. 2015a; Li et al. 2016a; Liu et al. 2012; Xu et al. 2015; Zhai et al.
738 2016).

760
761
762
763
764
765
766
767

In addition to the *tet* and *sul* genes, the occurrence of other ARGs including quinolone (*qnr*), macrolide resistance gene (*erm*) and multidrug-resistant New Delhi metallo- β -lactamase genes (NDM-1) have also been reported in the effluent and

768
769
770 dewatered waste sludge in STPs of northern China (Luo et al. 2014; Mao et al. 2015).
771
772 In recent years, high-throughput sequencing-based metagenomic analysis has been
773
774 applied to simultaneously investigate the broad-spectrum profiles and fate of ARGs in
775
776 STPs, yielding a significantly higher diversity of ARGs than could be demonstrated
777
778 by qPCR alone. For example, a total of 271 ARGs subtypes belonging to 18 ARGs
779
780 types were identified in a typical full-scale STP in Hong Kong (Yang et al. 2014).
781
782 Influent had the highest ARGs abundance, followed by effluent, anaerobic digestion
783
784 sludge and activated sludge (Yang et al. 2014). Seasonal and geographical distribution
785
786 of antibiotic resistome from Chinese urban sewage were also characterised based on
787
788 metagenomic analysis. The demographic "Hu Huanyong line" separated the regional
789
790 ARG burden into two main regions, suggesting human activities might be the major
791
792 driver of antibiotic resistance burden distribution (Su et al. 2017).

793
794 Extensive studies have illustrated the change in abundance of typical ARGs and
795
796 int11 in STPs of China (Chen and Zhang 2013a; Du et al. 2014; Ju et al. 2016; Li et al.
797
798 2016c; Mao et al. 2015; Pu et al. 2009; Wen et al. 2016). The removal efficiency
799
800 varied among different ARGs and different treatment processes. For example,
801
802 selected *tet* genes were significantly reduced by almost 2 to 3 orders of magnitude
803
804 (Chen and Zhang 2013b) which exceeds the removal efficiency observed for six
805
806 ARGs (0.3-2.7) (Wen et al. 2016). However, *tet* genes (1.2-2.7) were found to be
807
808 more readily lost in STP treatment than *sul* genes (<1) (Wen et al. 2016). Measuring
809
810 removal of ARGs from the STP influent by sampling the effluent is complicated by
811
812 the fact that ARGs accumulate in the sludge which has another disposal route into the
813
814 environment (Zhang and Zhang 2011). It has been reported that the total load of
815
816 ARGs discharged through dewatered sludge was 7 to 308 fold higher than that in the
817
818 raw influents and 16 to 638 fold higher than that in the final effluents (Wang et al.
819
820 2015). ARGs have also been shown to proliferate through biological treatment stages
821
822 (Du et al. 2014; Luo et al. 2014; Pu et al. 2009; Zhang et al. 2009a), such as
823
824 conventional activated sludge, due to microbial growth. Therefore, more advanced
825
826 technologies such as Advanced Oxidation Processes (AOPs) which have been
recommended to improve the removal of ARGs in STP (Chen and Zhang 2013a;

827
828
829 Zhang et al. 2016b).
831
832

833 4.2 ARGs in receiving aquatic environment 834

835 Discharges from STPs, antibiotic production plants, livestock farms and
836 aquaculture contribute to the ARBs and ARGs reported in aquatic environment.
837 However, it is largely unknown the extent to which each one contributes to the
838 ARGs/ARBs recovered in any particular location (Singer et al. 2016)
840

841 Many studies focused on antibiotic resistance within *Escherichia coli* in the
842 aquatic environment owing to its relevance to environmental standards and human
843 health. For example, *E. coli* resistant to one or more antibiotics among nine antibiotics
844 was screened from Wenyu River Basin in Beijing, China, with mean frequency of
845 48.7±8.7% of 388 isolates in summer and 47±6% of 236 isolates in winter. The
846 highest proportion of resistance appeared for sulfonamides, tetracycline, and
847 ampicillin (Hu et al. 2008a). *E. coli* isolates from several rivers in Southern China,
848 including Minjiang River, (Chen et al. 2011a) Dongjiang River (Su et al. 2012) and
849 Jiulongjiang River (Ou et al. 2015), were screened for susceptibility to a range of
850 antibiotics, and MDR. MDR was also found in strains of *E. coli* isolated from Taihu
851 Lake based on culture-dependent approaches (Zhang et al. 2015e). Through a
852 combination of culture-dependent approaches and qualitative PCR methods,
853 tetracycline, sulfonamide, fluoroquinolone, ampicillin, extended-spectrum beta-
854 lactamase-producing bacteria, chloramphenicol-resistant bacteria and associated
855 ARGs were detected in fresh and marine water in China (Dang et al. 2008; Li et al.
856 2010; Sun et al. 2012; Tao et al. 2010; Zou et al. 2012), supporting the hypothesis that
857 human activities contributed to the dispersal and maintenance of antibiotic resistance
858 in the aquatic environment in China.
859
860
861

863
864
865
866
867
868
869
870
871
872
873
874

875 Among the detected ARGs, *tet* and *sul* are the most common resistance genes
876 quantified by qPCR. For example, two sulfonamide ARGs (*sulI* and *sulIII*) and seven
877 tetracycline ARGs (*tetA*, *tetC*, *tetG*, *tetX*, *tetO*, *tetQ* and *tetM*) were quantified in 20
878 water samples collected in the Beijiang River, South China (Ling et al. 2013) The
879 levels of *sulI* were higher than *sulIII* ($p < 0.05$), with the mean values of (1.41 ± 1.12)
880
881
882
883
884
885

886
887
888
889 $\times 10^{-2}$ and $(1.58 \pm 1.71) \times 10^{-3}$ copies/16S rDNA, respectively. Among *tet* genes,
890 *tetC* had the highest concentration, ranging from 8.30×10^{-2} to 13.20 copies/16S
891 rDNA (Ling et al. 2013). Jiang et al. also quantified two sulfonamide ARGs (*suII* and
892 *suIII*), eight tetracycline ARGs (*tetA*, *tetB*, *tetC*, *tetG*, *tetX*, *tetO*, *tetQ* and *tetM*) and
893 one β -lactam ARG (TEM) in the Huangpu River, Shanghai, China (Jiang et al. 2013).
894 The average concentrations of ranged from 3.66×10^1 copies/mL (*tetB*) to 1.62×10^5
895 copies/mL (*suIII*). Lake water samples from the northern part of Taihu Lake contained
896 a significant number of *tetA* (10^4 – 10^5 copies/ml) *tetC* (10^5 copies/ml) genes and class
897 1 integron (10^3 copies/ml) (Zhang et al. 2009b). The absolute abundance of ARGs
898 (*suII*, *suIII*, *tetA*, *tetB*, *tetE*, *tetW*, *tetM* and *tetZ*) in the urban rivers in Beijing, China,
899 ranged from 7.0×10^1 to 5.9×10^6 copies/mL in surface water, and from 4.2×10^2 to
900 2.0×10^8 copies/g in the sediment (Xu et al. 2016). A positive correlation was observed
901 between *int1* and *suII* genes in many studies (Chen et al. 2015; Lin et al. 2015; Luo et
902 al. 2010; Na et al. 2014), confirming that the class 1 integron plays an important role
903 in the proliferation of the *suII* gene.
904
905
906
907
908
909
910
911
912
913
914
915

916 As compared to water samples, sediment samples can contain higher
917 concentrations of ARGs. For instance, Luo *et al* showed that *suII* and *suIII*
918 concentrations in sediments were 120 to 2000 times higher than those in water
919 collected from the Haihe River in China (Luo et al. 2010). Similar results were also
920 found in samples from the Northern Yellow Sea where the *suII* and *suIII*
921 concentrations in sediments were 10^3 times higher than those in water, indicating
922 sediment was an important reservoir of some ARGs (Na et al. 2014). On a volumetric
923 basis, the Taihu lake sediments contained higher concentrations of *intI1*, *tetA* and *tetC*
924 genes by four to five orders of magnitude than the overlying water samples. While
925 copy numbers normalized to DNA mass from sediment samples were similar to those
926 from water samples, which highlights the question of the most informative measure of
927 ARG abundance (Zhang et al. 2009b). In this particular case, it might be that
928 differences in the microbial diversity between the sediment and the overlying
929 freshwater or the differential extractability of DNA from the two matrices impacts the
930 comparisons. Tetracycline, sulfonamide, and macrolide resistance genes, as well as
931
932
933
934
935
936
937
938
939
940
941
942
943
944

945
946
947
948 integrons in the sediments were also detected at a catchment scale (Dongjiang River
949 basin of South China), and *suII* was the most abundant resistance gene, with the
950 concentration of 10^8 copies/g (Su et al. 2014a).
951

952
953 The resistance genotype and mechanisms recovered by metagenomics in the
954 sediments from the highly human-impacted Pearl River Estuary (PRE) and the
955 relatively pristine deep South China Sea (SCS) were more diverse and the ARG
956 abundance was much higher in the polluted PRE sediments than in the relatively
957 pristine SCS sediments (Chen et al. 2013a). In comparison, the three most abundant
958 ARGs in the PRE sediments were related to commonly used antibiotics including
959 sulfonamides, fluoroquinolones, and aminoglycosides, indicating the significant
960 anthropogenic impact on the dissemination of ARGs in this region (Chen et al.
961 2013a). Culture-based methods and high-throughput qPCR quantified, the abundance
962 of MDR bacteria and ARGs in water samples collected from an urban stream and
963 source of Jiulongjiang River, China. The total abundance of ARGs in urban samples
964 (ranging from 9.72×10^{10} to 1.03×10^{11} copies/L) was over two orders of magnitude
965 higher than that in pristine samples (7.18×10^8 copies/L) (Ouyang et al. 2015). ARGs
966 were also profiled in sediments from 18 estuaries over 4,000 km of coastal China
967 (Zhu et al. 2017). The high abundance and enrichment of diverse ARGs and MGEs
968 further demonstrated the contribution of anthropogenic activities to the emergence
969 and dissemination of ARGs (Ouyang et al. 2015; Zhu et al. 2017).

984 *4.3 ARGs in livestock farm wastes*

985
986 Livestock manure has routinely been shown to be an important reservoir of
987 resistant bacteria (Bibbal et al. 2007; Enne et al. 2008; Schwaiger et al. 2009),
988 antibiotic resistance genes (Binh et al. 2010; Duriez and Topp 2007; Heuer et al.
989 2008) and transferable plasmids carrying ARGs (Binh et al. 2008; Heuer et al. 2009).
990 Livestock waste has been shown to be a hotspot of antibiotic residues that can affect
991 the gut microbiota of animals and perpetuate the increased prevalence of antibiotic
992 resistance in bacteria in manure (Langford et al. 2003; Looft et al. 2012; Witte 2000).
993
994
995
996
997

998 In China, the most frequently reported studies on animal manures are on swine,
999 chicken and cattle which are the major food-producing animals. Resistant bacteria
1000

1004
1005
1006
1007 isolated from these animals have largely been reported based on the culture-dependent
1008 assays. For example, Yang et al. (Yang et al. 2004) analysed the antimicrobial
1009 susceptibility of *E. coli* isolates from pig and chicken farms in Beijing and Hebei
1010 Province, China in 2000 and found that most *E. coli* isolates were resistant to multiple
1011 classes of antimicrobials. Isolates displayed resistance to tetracycline (98%),
1012 sulfamethoxazole (84%), ampicillin (79%), streptomycin (77%), and trimethoprim-
1013 sulfamethoxazole (76%). Fluoroquinolones resistance in *E. coli* ranged from 64% for
1014 levofloxacin, 79% for ciprofloxacin, and 95% for difloxacin. Meanwhile, class 1
1015 integrons were also identified in 19% (17) of isolates from swine and 47% (42) of
1016 isolates from chickens. Similar findings have been reported for *E. coli* isolates from
1017 cattle, swine and chicken farms in Shandong Province, Eastern China, where 52% of
1018 chicken isolates, 25% of swine isolates and 30% of cattle isolates were resistant to 12,
1019 10 and 1 antimicrobial agents, respectively. The percentage of class 1 gene cassette-
1020 positive isolates in dairy cattle, swine and chicken farm was 5%, 20% and 42%,
1021 respectively. Resistance rates of chicken farm isolates were highest (Lu et al. 2010b).
1022 In addition to the intensively farmed animals, a total of 129 *E. coli* and 84
1023 *Enterococcus* isolates from free-ranging pigs also showed resistance to a variety of
1024 antibiotics in Tibet, indicating AMR bacteria in China is widespread (Li et al. 2014b).

1030
1031
1032
1033

1034 Tetracycline and sulfonamide resistance genes and the class 1 integrase gene
1035 were widely reported in livestock manures. Ji et al. quantified eight ARGs (*tetB* (P),
1036 *tetM*, *tetO*, *tetW*, *sulI*, *sulII*, *sulIII* and *sulA*) in manure samples from representative
1037 swine, poultry and cattle feedlots in Shanghai, China (Ji et al. 2012). All ARGs tested
1038 were detected in the collected samples except *tetB*(P). The relative abundance of
1039 sulfonamide and tetracycline resistance genes ranged from approximately 10^{-5} to
1040 10^{-2} , and 10^{-6} to 10^{-3} , respectively. Overall, sulfonamide ARGs were more abundant
1041 than tetracycline ARGs and only a weak positive correlation was found between
1042 ARGs and their corresponding antibiotics except for *sulIII* (Ji et al. 2012). Cheng et al.
1043 investigated the abundance and diversity of ten *tet* genes (*tetA*, *tetB*, *tetC*, *tetG*, *tetL*,
1044 *tetM*, *tetO*, *tetQ*, *tetW*, and *tetX*), two *sul* genes (*sulI* and *sulII*), and class 1 integron
1045 (*intI1*) in eight livestock farms in Hangzhou, eastern China. No significant difference

1058
1059
1060
1061
1062

1063
1064
1065
1066 was found in the abundance of the *tet* and *sul* genes among similar farm types with
1067 varying scales ($P > 0.05$). *tetQ* had the highest relative abundance in all manure
1068 samples (the average abundance was $7.12 \times 10^{-2} \pm 2.99 \times 10^{-2}$ ARG copies/16S rRNA
1069 copies), followed by three ribosomal protection protein (RPP) genes (*tetM*, *tetW*, and
1070 *tetO*), with *tetC* having the least relative abundance in their study (Cheng et al. 2013).
1071 *tet* and *sul* genes were widely reported in animal manure from many other cities of
1072 China (Cheng et al. 2016; Wang et al. 2016a; Zhang et al. 2015d). Quinolone-,
1073 macrolide-, aminoglycoside-, and MDR-genes were also analysed in concentrated
1074 livestock feedlots of China (Mu et al. 2015; Wang et al. 2016b). With the
1075 development of culture-independent methods, including high- capacity q-PCR and
1076 metagenomics, hundreds of resistance genes and multiple samples can be detected
1077 simultaneously. For example, Zhu et al. used high-capacity qPCR with 313 validated
1078 primer sets, which target 244 ARGs from all major classes of ARGs, to assess types
1079 and concentrations of ARGs at three stages from manure processing to land disposal
1080 at three large-scale swine farms. 149 unique resistance genes were detected and 63
1081 ARGs were enriched from 192-fold (median) up to 28,000-fold (maximum) as
1082 compared with their respective antibiotic-free manure or soil control. The potential for
1083 horizontal transfer of ARGs was implicated by the enrichment of transposases—the
1084 top six alleles being enriched 189-fold (median) up to 90,000-fold in manure (Zhu et
1085 al. 2013b). Li et al. used a metagenomic approach to investigate the wide-spectrum
1086 profiles of ARGs and their co-occurrence pattern in a range of environmental
1087 samples. ARG abundances were consistent with the levels of anthropogenic impacts
1088 on these environments (Li et al. 2015).

1105
1106

1107 1108 1109 *4.4 ARGs in Soil*

1110
1111 The soil is one of the largest and most diverse microbial habitats on earth and a
1112 natural habitat for the Actinomycete genus *Streptomyces*, whose species account for
1113 the majority of mass-produced antibiotics of natural origin. Soil microbiota represent
1114 an ancient evolutionary origin for antibiotic resistance (D'Costa et al. 2011; Forsberg
1115 et al. 2012). The transfer of environmentally-derived antibiotic resistance genes into
1116
1117
1118
1119
1120
1121

1122
1123
1124
1125 clinical pathogens has been a long argued aetiology of clinical ARGs (Benveniste and
1126 Davies 1973). However, the high antibiotic residues caused by human activities
1127 significantly accelerates the selection and expansion of the bacterial resistome in the
1128 soil (Graham et al. 2016).
1129

1130
1131
1132 In China, manure and/or manure-based compost application as fertiliser is one of
1133 the main pathways for antibiotics release into agricultural soils. Many studies reported
1134 a noticeable increase in ARGs diversity and abundance in soils that received long-
1135 term applications of livestock manure (Chen et al. 2016; Cheng et al. 2016; Ji et al.
1136 2012; Mu et al. 2015; Wang et al. 2014d; Wu et al. 2010; Zhang et al. 2015d; Zhou et
1137 al. 2017). Sulfonamide and tetracycline resistance genes have frequently been
1138 detected in manure or composted manure-amended soils (Cheng et al. 2016; Ji et al.
1139 2012; Peng et al. 2015; Wang et al. 2014d; Wu et al. 2010; Zhang et al. 2015d; Zhou
1140 et al. 2017). Extended-spectrum beta-lactamase (ESBL)-producing *E. coli* have also
1141 been detected from a pig farm in the rural regions of Tai'an, China and the ESBL-
1142 producing isolates from compost, treated soil, and manure showed high overlaps in
1143 terms of resistance phenotypes, ESBL genes, plasmid replicon type, and genomic
1144 backbone characterization, which implies the dissemination of ARB and ARGs of
1145 animal origins to soil after treated with animal manure (Gao et al. 2015). The
1146 dissipation of plasmid-mediated quinolone resistance (PMQR) genes in arable soil
1147 were slowed down by introducing (fluoro) quinolones (FQNs)-containing manure as
1148 reported in a soil microcosm experiment (Xiong et al. 2015). Based on the functional
1149 metagenomic approach, Su et al. identified multiple ARGs, with the majority of
1150 ARGs recovered from manure-amended soil. The results suggest manure amendment
1151 increases the diversity of ARGs in soil bacteria (Su et al. 2014b). Fang et al.
1152 investigated the diversity and abundance of ARGs, human pathogenic bacteria (HPB),
1153 and HPB carrying ARGs in chicken manures and greenhouse soils. The highest
1154 relative abundance was tetracycline resistance genes (manures) and multidrug
1155 resistance genes (greenhouse soils). A positive correlation was also observed between
1156 the levels of antibiotics, ARGs, HPB, and HPB carrying ARGs in manures and
1157 greenhouse soils (Fang et al. 2015).

1179
1180

1181
1182
1183
1184 Irrigation water quality is another important factor in stimulating ARGs in soil
1185 besides manure application. Chen et al. collected non-irrigated and wastewater-
1186 irrigated soils from five wastewater irrigation areas in Beijing and Tianjin, China and
1187 analysed the abundances of antibiotic-resistant bacteria and thirteen *tet* and three *sul*
1188 resistance genes. No significant difference in antibiotic resistance bacteria was
1189 observed between irrigated and non-irrigated soils. However, the concentrations of
1190 antibiotics and abundances of ARGs were significantly greater in irrigated soils,
1191 indicating the potential role of quality of water on the occurrence of antibiotics
1192 and resistance genes in the soils (Chen et al. 2014). Wang et al. used high-capacity
1193 qPCR to show enrichment of ARGs in urban park soils as a result of reclaimed water
1194 irrigation. A total of 147 ARGs encoding for resistance to a broad-spectrum
1195 of antibiotics were detected among all park soil samples. Aminoglycoside and beta-
1196 lactam were the two most dominant types of ARGs, and antibiotic deactivation and
1197 efflux pump were the two most dominant detoxification mechanisms. Four
1198 transposase genes were also detected and were positively correlated with ARGs and
1199 transposase abundances, indicating the potential facilitation of ARGs transfer (Wang
1200 et al. 2014b).

1201
1202
1203
1204
1205
1206
1207
1208
1209
1210
1211
1212
1213
1214 As antibiotics can migrate to deeper soil layers, an abundance of ARGs with
1215 increasing soil depths was observed in some studies (Tang et al. 2015). Selection for
1216 ARGs in soils amended with antibiotics free manure was previously reported, a likely
1217 result of the co-selective pressure provided by heavy metals that can also be present in
1218 manure at high levels (Lin et al. 2016). Therefore, considering the various soil types,
1219 climatic regions, and cultivation conditions of China, more field studies should be
1220 conducted to identify the relative contribution of each of the factors that influence the
1221 fate of ARGs.

1226
1227
1228
1229
1230
1231
1232
1233
1234
1235
1236
1237
1238
1239
Significant positive correlations between ARGs and corresponding antibiotics or
a different class of antibiotics were found in multiple environmental media in China
(Cheng et al. 2016; Huang et al. 2013a; Luo et al. 2010; Su et al. 2014a; Wang et al.
2016a; Wu et al. 2010; Zhu et al. 2013b). While weak or no correlation was also
reported in many studies (Ji et al. 2012; Pei et al. 2006; Wang et al. 2016a; Wang et

1240
1241
1242
1243 al. 2016b). The inconsistencies in the correlations between antibiotics and ARGs can
1244 be attributed to several factors. First, ARGs and antibiotics have different
1245 environmental fate and transport mechanisms. The environmental degradation of
1246 antibiotics and the physicochemical parameters of environmental media, e.g. total
1247 organic matter, may affect the correlation analysis results (Wang et al. 2016b). ARGs
1248 could have been primarily selected by past activities and microbial populations may
1249 retain resistance genes long after their initial exposure, which could contribute to the
1250 lack of direct correlation (Hall and Colegrave 2008). Additionally, co-selection and
1251 cross-selection effects could also disrupt the correlations (Wardwell et al. 2009).
1252 Many ARGs are often found on the same plasmid or mobile genetic elements which
1253 results in the correlations found among resistance to different antibiotics. Heavy
1254 metals can exert a co-selection pressure for antibiotic resistance also because both the
1255 antibiotics and heavy metal resistance genes are commonly found to be encoded on
1256 mobile genetic elements together (Berg et al. 2010). Therefore, further studies should
1257 be carried out to illustrate the exact reasons of the correlations.

1270 **5. Antibiotic resistance in the clinical environment**

1271

1272 Antibiotics are among the most commonly prescribed drugs used in human
1273 medicine, enabling antibiotic resistance to emerge as the serious public health crisis
1274 that it has become (Li et al. 2016b; Zeng et al. 2017). The growth rate of resistance in
1275 China is much higher than that of other countries, averaging 22% in 6 years (1994–
1276 2000) compared with 6% for the USA (1999–2002) (Zhang et al. 2006). Excessive
1277 and often unnecessary use of antibiotics is considered to be the major driving force
1278 towards increased antibiotic resistance in clinic settings. Additionally, the frequent
1279 use of broad-spectrum antibiotics and the frequent change of antibiotics can
1280 contribute to the antibiotic resistance, especially the multi-drug resistance strains
1281 (Ding et al. 2008).
1282
1283
1284
1285
1286
1287
1288

1289
1290 In 2004, the Chinese Ministry of Health (MOH) National Antibacterial
1291 Resistance Investigation Net (Mohnarin) was established—a nationwide antimicrobial
1292 resistant surveillance network. Initially, seventeen tertiary hospitals located in 15
1293
1294
1295

1299
1300
1301
1302 different cities throughout China participated in the network (Xiao et al. 2008).
1303
1304 Mohnarin has gradually expanded to more than one thousand member hospitals and in
1305
1306 2014, the network became the China Antimicrobial Resistance Surveillance System
1307
1308 (CARSS). To date, CARSS remains the only government-leading surveillance
1309
1310 network in China and it includes 1412 member hospitals from 31 provincial-level
1311
1312 administrative units, representing the widest coverage in China. In the CARSS 2015
1313
1314 report, it demonstrated the presence of severe bacterial resistance in China. A total of
1315
1316 2,400,786 strains of culturable bacteria in samples (sputum, blood, urine, stool, etc.)
1317
1318 from outpatients and inpatients were detected in the surveillance program from
1319
1320 October 2014 to September 2015, including 695,066 Gram-positive bacteria (28.9%)
1321
1322 and 1,705,720 Gram-negative bacteria (71.1%). The five most frequently detected
1323
1324 Gram-positive strains are: *Staphylococcus aureus*, *Staphylococcus epidermidis*,
1325
1326 *Enterococcus faecalis*, *Streptococcus pneumoniae* and *Enterococcus faecium*, *E. coli*,
1327
1328 *Klebsiella pneumoniae*, *Pseudomonas aeruginosa*, *Acinetobacter baumannii* and
1329
1330 *Enterobacter cloacae* are the five most frequently detected Gram-negative bacteria
1331
1332 five gram-negative bacteria. The resistance rates of methicillin-resistant
1333
1334 *Staphylococci*, erythrocine-insensitive *S. pneumoniae*, cephalosporin-resistant
1335
1336 *Enterobacteriaceae*, fluoroquinolone-resistant *E. coli* and carbapenems-resistant *A.*
1337
1338 *baumannii* were all more than 50% in the CARSS 2015 report. Of growing concern is
1339
1340 the increase in resistance to imipenem reported in *A. baumannii* and *K. pneumoniae*
1341
1342 between 2012 and 2015 (CARSS et al. 2016). Another nation-wide surveillance
1343
1344 system, CHINET, was organised in 2005 by Fudan University. It analysed the
1345
1346 temporal trend of bacterial resistance in samples (sputum, urine, blood, cerebrospinal
1347
1348 fluid, stool, etc) from outpatients and inpatients in 19 hospitals between 2005 and
1349
1350 2014 (two hospitals dropped out in 2012) (Hu et al. 2016a). Most of the hospitals
1351
1352 included are the largest in each province or city, representing 14 provinces or cities.
1353
1354 During the study period, the number of bacterial isolates ranged between 22,774 and
1355
1356 84,572 annually. The resistance of *E. coli* and *K. pneumoniae* to amikacin,
1357

1358
1359
1360
1361 *pneumoniae* and *A. baumannii* isolates both increased significantly between 2005 and
1362 2014. In the latest CHINET 2015 report, it collected a total of 88,778 clinical isolates
1363 from similar samples (sputum, urine, blood, cerebrospinal fluid, stool, etc.) in 18
1364 general hospitals and two children's hospitals. Gram-negative organisms and Gram-
1365 positive cocci accounted for 70 % and 30 %, respectively. The prevalence of
1366 carbapenem-resistant *K. pneumoniae* and *A. baumannii* continues to increase on 2014
1367 levels, similar to that which was reported in the CARSS report (Hu et al. 2016b). The
1368 carbapenem family of antibiotics is the last resort for most Gram-negative bacterial
1369 infections. Therefore, infections due to carbapenem-resistant strains become an
1370 increasingly serious threat to patients in clinics.
1371
1372
1373
1374
1375
1376
1377
1378

1379 There are also several provincial surveillance systems, such as in Beijing,
1380 Zhejiang, and Guangzhou. And a number of studies have shown the emergence of
1381 antibiotic-resistant bacterial strains, including multi-drug resistance of bacteria, in
1382 Chinese hospitals during the past decades (Chen et al. 2013b; Dai et al. 2014; Liang et
1383 al. 2015; Song et al. 2014; Tang et al. 2016; Xia et al. 2012). However, the current
1384 survey system mainly focuses on urban hospitals and does not include the county or
1385 rural medical institutions. For example, in the CARSS 2015 report, 76.2% of the
1386 member hospitals are tertiary hospitals and 23.8% are secondary hospitals. Taking
1387 into account different socioeconomic development, prescription behaviour, etc., it is
1388 apparent that antibiotic resistance varies geographically in China. Only a few studies
1389 reported resistance prevalence in county medical institutes (Xiao et al. 2015).
1390
1391
1392
1393
1394
1395
1396
1397
1398
1399

1400 In general, the survey systems are based on culture-dependent methods to detect
1401 the antibiotic resistance in clinics, while isolated studies have characterised
1402 antimicrobial resistance using molecular biology approaches (Cui et al. 2015; Yang et
1403 al. 2015; Zhang et al. 2016a). The most common resistance mechanism of
1404 carbapenem is the production of carbapenemases, including enzymes of Ambler
1405 classes A, D and B [metallo- β -lactamases (MBLs)], with the corresponding genes
1406 often being associated with mobile genetic elements. New Delhi MBL 1 (NDM-1), a
1407 new type of MBL, was first reported in *A. baumannii* isolates in four different
1408 provinces in China (Chen et al. 2011b). Later, PCR based detection of carbapenem
1409
1410
1411
1412
1413
1414
1415
1416

1417
1418
1419
1420 resistance associated gene(*bla_{NDM-1}*) unveiled high incidence and sporadic spread of
1421 *bla_{NDM-1}*-positive *Enterobacteriaceae* in many provinces of China (Hu et al. 2013; Liu
1422 et al. 2013; Qin et al. 2014; Sun et al. 2014). Jia et al. detected the β -lactam,
1423 aminoglycoside, tetracycline, macrolide, glycopeptide resistance genes and the efflux
1424 pump genes in 100 multiple-drug resistant enterococcal isolates from a university
1425 hospital in China and indicated that the emergence of these antibiotic resistance genes
1426 was the main cause of the resistance of enterococci to antimicrobial agents (Jia et al.
1427 2014). High throughput assays such as microarray technology were also applied to
1428 determine multiple tetracycline and β -lactam resistance genes from the sputum, urine,
1429 blood, bile, liquor puris, and cerebrospinal fluid samples obtained from Chinese
1430 hospitals (Lu et al. 2010a). With the emergence and spread of new mechanisms of
1431 resistance, infectious diseases are becoming more difficult to treat in China.
1432
1433
1434
1435
1436
1437
1438
1439
1440

1441 1442 1443 **6. Prospective and Mitigation strategies** 1444

1445 Numerous studies have detected ARB and ARG in a variety of environmental
1446 media in China and the increasing prevalence of antibiotic resistance in the
1447 environment has attracted greater attention from academia and government.
1448 Antibiotic overuse and misuse is likely the most important reason for the observed
1449 increased prevalence in environmental and clinical antimicrobial resistance.
1450 Therefore, the first and most important measure would be reducing unnecessary use
1451 of antibiotics to tackle this problem at the source.
1452
1453
1454
1455
1456

1457 For clinical use of antibiotics, although China has released a series of regulations
1458 and strategies to reduce the rate of antibiotic prescriptions during the last decades,
1459 inappropriate prescription continues in China, especially in the primary care settings
1460 in rural areas. Financial incentives are considered to be the main driver of this over-
1461 prescription in China. The Chinese government has recently launched reforms to
1462 address these drivers. For example, on April 8, 2017, Beijing started a landmark
1463 reform drive that will separate drug sales from medical treatment at public hospitals.
1464 This separation is intended to stop over-prescription and help medical practitioners
1465 provide more appropriate treatment. Since public hospitals provide over 90% of the
1466
1467
1468
1469
1470
1471
1472
1473
1474
1475

1476
1477
1478
1479 country's inpatient services and more than 50% of outpatient services, it is imperative
1480 that greater efforts are needed to pursue health system reform for public hospitals to
1481 alter the inappropriate finance incentives.
1482

1483
1484 At least as many antibiotics are used in agriculture than in humans in China, and
1485 even some last-line drugs for humans are being used in agriculture. Colistin, for
1486 example, has been banned as a growth stimulator in agriculture on Nov1, 2016 and
1487 the ban took effect on April 1, 2017. The experiences exemplified by the reduction in
1488 antibiotic use in Denmark and The Netherlands in pig farming can provide instructive
1489 case studies on the effects of reduced antibiotic use in animal food production
1490 (Aarestrup et al. 2001; Dierikx et al. 2016). The World Health Organization has found
1491 that the Danish ban reduced human health risk without significantly harming animal
1492 health or farmers' incomes (WHO 2003). Antibiotic sales to Dutch livestock farms
1493 decreased by 56% without any reduction in production or profits from 2007 to 2012
1494 (McKenna 2014). Therefore, alternative strategies for the control of bacterial
1495 infections, such as optimise the living conditions of livestock, are required to reduce
1496 antibiotic consumption in food animals in China.

1506

1507
1508 Secondly, a systematic surveillance network should be established that includes
1509 regular, continuous measurement of antibiotic utilisation and the patterns of antibiotic
1510 resistance from the clinic and agriculture, at a local and national level. Surveillance
1511 was recognised as the first step to understanding the current state and progression of
1512 resistance over time. Although there are some existing surveillance programs for
1513 ARBs in China, they are not inclusive of the primary care settings. Continuous
1514 surveillance of antibiotic resistance can contribute to disease diagnosis, treatment and
1515 policy making. Reliance on sales data for antibiotic surveillance can tell an
1516 incomplete story; hence a nationwide surveillance program is needed to quantify
1517 antibiotic prescriptions from all sources i.e., pharmacies, clinics, hospitals. Unlike
1518 human use antibiotics, some veterinary antibiotics can be purchased directly by food
1519 animal producers. Thus, it's difficult to quantify accurately veterinary antibiotic use.
1520 A robust antibiotic surveillance system can facilitate the enforcement of the restriction
1521 on the use of antibiotics in animals that are important for human use. It can also

1534

1535
1536
1537
1538 monitor the association between antibiotic use and resistance, as well as inform
1539 intervention in much the same way that the surveillance system, DANMAP, has made
1540 significant contributions to the control of antibiotic resistance in Denmark (Bager
1541 2000). Antibiotic use in animals should be confined to prescription and dispensed by
1542 veterinarians for treatment and not by the whim of the farmer for other purposes. For
1543 a surveillance system in China, there needs to be consistency in sampling and testing
1544 methods. Strict quality control should also be applied in order to compare trends in
1545 antibiotic resistance. The surveillance program should be publicly available,
1546 facilitating open science which can bring greater understanding by academia and
1547 innovation by industry.

1555
1556 It is critically important to control the environmental spread of antibiotics and
1557 ARBs, especially for STPs, which provide favourable conditions for proliferating of
1558 ARBs or transferring of ARGs. As conventional sewage treatment facilities were not
1559 designed to deal with antibiotics, the removal efficiencies of antibiotics were highly
1560 variable among different antibiotics and different STPs. So far, AOPs are not widely
1561 used in STPs because of the high cost, and conventional STPs were even absent in
1562 rural areas in China. It's urgent to reinforce the operation of STPs in rural areas and
1563 the application of more advanced techniques in urban STPs to improve the effluent
1564 quality. Current technologies are unable to provide complete removal or destruction
1565 of antibiotics which are subsequently transferred to sludge during sewage biological
1566 treatment. Further treatment is also needed for these solid matrices. Maximum residue
1567 limits for antibiotics in effluent and sludge of STP or animal manure in China should
1568 be implemented in the environment. Although beyond the scope of this review,
1569 similar residue limits might be appropriate for metals and biocides to address the
1570 challenge of co-selection. Some rules should be established to reduce the use of
1571 sewage sludge or animal manure on agricultural land, thereby reducing the risk of
1572 spreading resistance in the environment to humans, food crops and wildlife. There is
1573 also a need to identify the levels of antibiotics at which resistance might occur and
1574 develop maximum thresholds for antibiotics or ARGs for environmental
1575 compartments.

1594
1595
1596
1597 In August 2016, China presented its National Action Plan to Contain
1598 Antimicrobial Resistance (2016-2020). The Action Plan aims to establish
1599 comprehensive management strategies and measures at the national level to
1600 strengthen the supervision of the search and development, production, circulation,
1601 application, and environmental protection for the antimicrobial agents (Xiao and Li
1602 2016). For the first time, 14 departments, including National Health and Family
1603 Planning Commission, National Development and Reform Commission, the
1604 Ministry of Environmental Protection, the Ministry of Agriculture were involved and
1605 collaborated to address AMR. The responsibilities of each department and nine major
1606 strategies for the prevention and control of antimicrobial resistance were clearly
1607 assigned in the Action Plan, including exploiting the advantages of joint prevention
1608 and control; increasing investment in the research and development of antimicrobials;
1609 strengthening the management of antibacterial agents supply security; strengthening
1610 the construction of antibacterial agent application and antimicrobial resistance control
1611 system; optimizing antimicrobial consumption and resistance surveillance system;
1612 improving the capacity of professional personnel in antimicrobial resistance
1613 prevention and control; strengthening the prevention and management
1614 of environmental pollution of antimicrobials; strengthening publicity and education of
1615 AMR; conducting extensive international change and cooperation. Actions have
1616 already taken place within the country under this plan. For example, the Ministry of
1617 Agriculture in China announced the 2017 Antimicrobial Resistance Surveillance
1618 Program of Bacteria from Food Animals. China has participated in
1619 extensive international collaborative programs to fight antibiotic resistance. At the
1620 G20 summit (September, 4-5, 2016) in Hangzhou, China, world leaders reached an
1621 important agreement on next steps in the battle with antimicrobial resistance. As the
1622 most populous and the largest consumer of antibiotics in the world, China faces the
1623 most significant challenge of any country when it comes to tackling antimicrobial
1624 resistance. Recent efforts at the national and international level must be seen as only
1625 the start of a growing commitment to the implementation of a One Health AMR
1626 Action Plan in all of China.
