Foreword

A comprehensive catalogue of underground temperature, heat flow and geochemical data was first prepared in 1977 by the British Geological Survey and published by the Department of Energy in 1978. Since that first edition of the Catalogue of geothermal data, two revisions have been published by BGS. The first in 1982, incorporated data acquired between June 1977 and August 1981, and comprised listings of underground temperatures, heat flow and geochemistry. Unlike the first edition, no temperature maps were included.

The second revision, published in 1984, was more extensive, incorporating new data for the period August 1981 to April 1984 as well as all previous data. A heat flow map was included but no temperature maps.

This third revision of the catalogue includes all new data collected between May 1984 and April 1987, and all the new heat flow observations made as part of the 1984 - 1987 Geothermal Programme. Abstraction of much of the temperature data has been by S. J. Self and B. C. Chacksfield, who also assisted in the validation, editing and compilation, using programs written by K. E. Rollin, who also wrote the text. Access to commercial log records, even for BGS, has become increasingly restricted, so that the temperature observations (Tables 1 and 2) should not be considered as a full record of all sub-surface temperature measurements made in the UK. Nevertheless, this revision contains temperature data for over 250 sites not listed in previous editions. A full listing is given for the new temperature data only, in a format similar to that of the last revision. A summary of all sites which provide sub-surface temperatures is given in Table 2. The UK thermal conductivity data are summarised in Table 3 while Table 4 is a compilation of the UK heat flow data and Table 5 a list of the new geochemical data compiled by W. G. Darling. The work has been supervised by R. A. Downing under the general direction of R. T. Haworth.

1 Introduction

A comprehensive geothermal database is essential for many aspects of geothermal research, including the modelling of sub-surface temperature fields and resource assessment. As part of the 1984-1987 geothermal programme, BGS has maintained and expanded all aspects of the geothermal database, and the main components - temperature, heat flow, thermal conductivity and geochemistry - are briefly described here. A brief explanation of the modifications and extensions to the data base is given in each of the sections 2 to 5. The results are presented as Tables 1-5. Table 1 gives the supplementary temperatures abstracted in the period 1984/87 in a form similar to that of Table I in the second revision (Burley, Edmunds and Gale 1984) and Table 2 gives a summary listing of all sites for which sub-surface temperature data are available. Table 3 summarises the thermal conductivity data, and Table 4 the UK heat flow data. The new geochemical data are listed in Table 5. This Catalogue uses the categories of temperature and heat flow data identified in the second revision, and a full description is not given here.

2 Temperature data

The second revision of the Catalogue of Geothermal Data (Burley, Edmunds and Gale 1984), contained sections on heat flow, temperatures and geochemistry. The revision contained over 1600 sub-surface temperature observations made at over 900 sites (boreholes, mines and shafts). Predominantly these were bottom hole temperature (BHT) observations (50%), with only 25% either equilibrium measurements or drill stem tests. The modal depth of these data was relatively shallow, less than 500m (Figure 1).

Since 1984, there has been considerable onshore commercial drilling activity, mainly for hydrocarbons, with the result that over 950 new temperatures have been added to this latest revision of the Catalogue. These new data, from over 250 sites, have a modal depth greater than 1500m (Figure 1), although the total dataset still has a relatively shallow distribution, with 93% from depths of less than 2000m. Only one borehole onshore is deeper than 4000m.

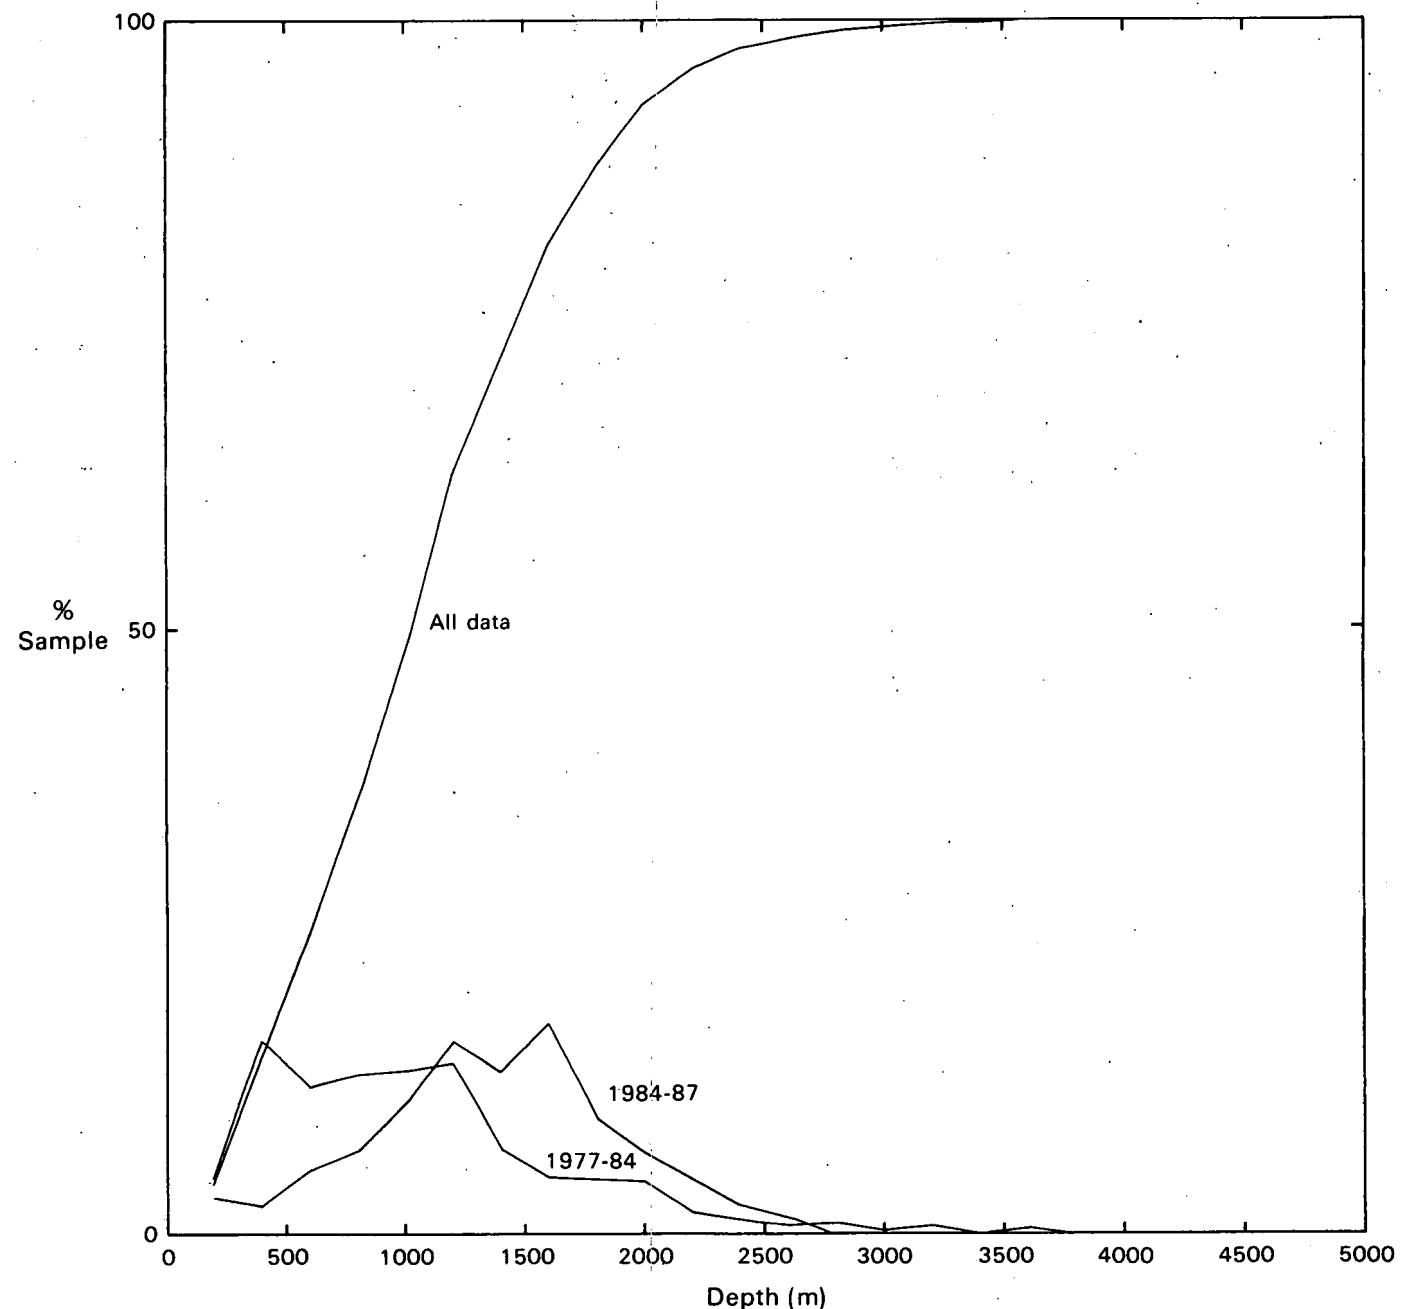

Figure 1 Frequency analysis of sub-surface temperature data for the UK, showing the distribution of data with depth.

Data abstraction

The majority of the new data (Table 1) are BHT observations, made during geophysical logging of commercial boreholes. Advances in drilling technology, together with an increase in the number of development wells, have meant that much of the new data has come from deviated boreholes. This has necessitated new formats for abstracting data and new routines to calculate total vertical depths. All depths listed in Tables 1 and 2 refer to vertical depths below ground level.

For the boreholes listed in Table 1, the BHT observations for each tool in each logging run, have been abstracted from the geophysical log header records where available. During the validation of data, the BHT data in each logging run were checked for consistency and the tool with the longest lapsed time since borehole circulation ended, has generally been used to provide the best BHT data for each logging run. For each logging run the recorded drilled depth can vary slightly. This leads to several records of BHT data at very similar depths in Table 1. The routine recording of driller's depth, logger's depth and bottom logged interval, provided a check on the true downhole depth for the BHT.

Temperature correction

In the last revision of the Catalogue, equilibrium temperatures were estimated from single BHT observations using empirical correction curves based on the lapsed time since circulation ended and the range of the observed temperature. This method produces discontinuities in the temperature correction, depending on the magnitude of the observed temperature, and a new empirical correction procedure has been used here. All BHT data with a post-circulation time (t) greater than or equal to 5 hours, have been corrected using the factor $(1+1/t+1/t^2)$. This gives a reasonable approximation to equilibrium temperatures from BHT, for a range of depths in the Winterborne Kingston borehole (Figure 2) and for selected wells in the North Sea (see Rollin 1986). Using this method, the correction time for a post-circulation time of 10 hours would be 1.11; this compares with a constant factor of 1.25 used by Oxburgh and Andrews-Speed (1981) and 1.15 used by Andrews-Speed and others (1984).

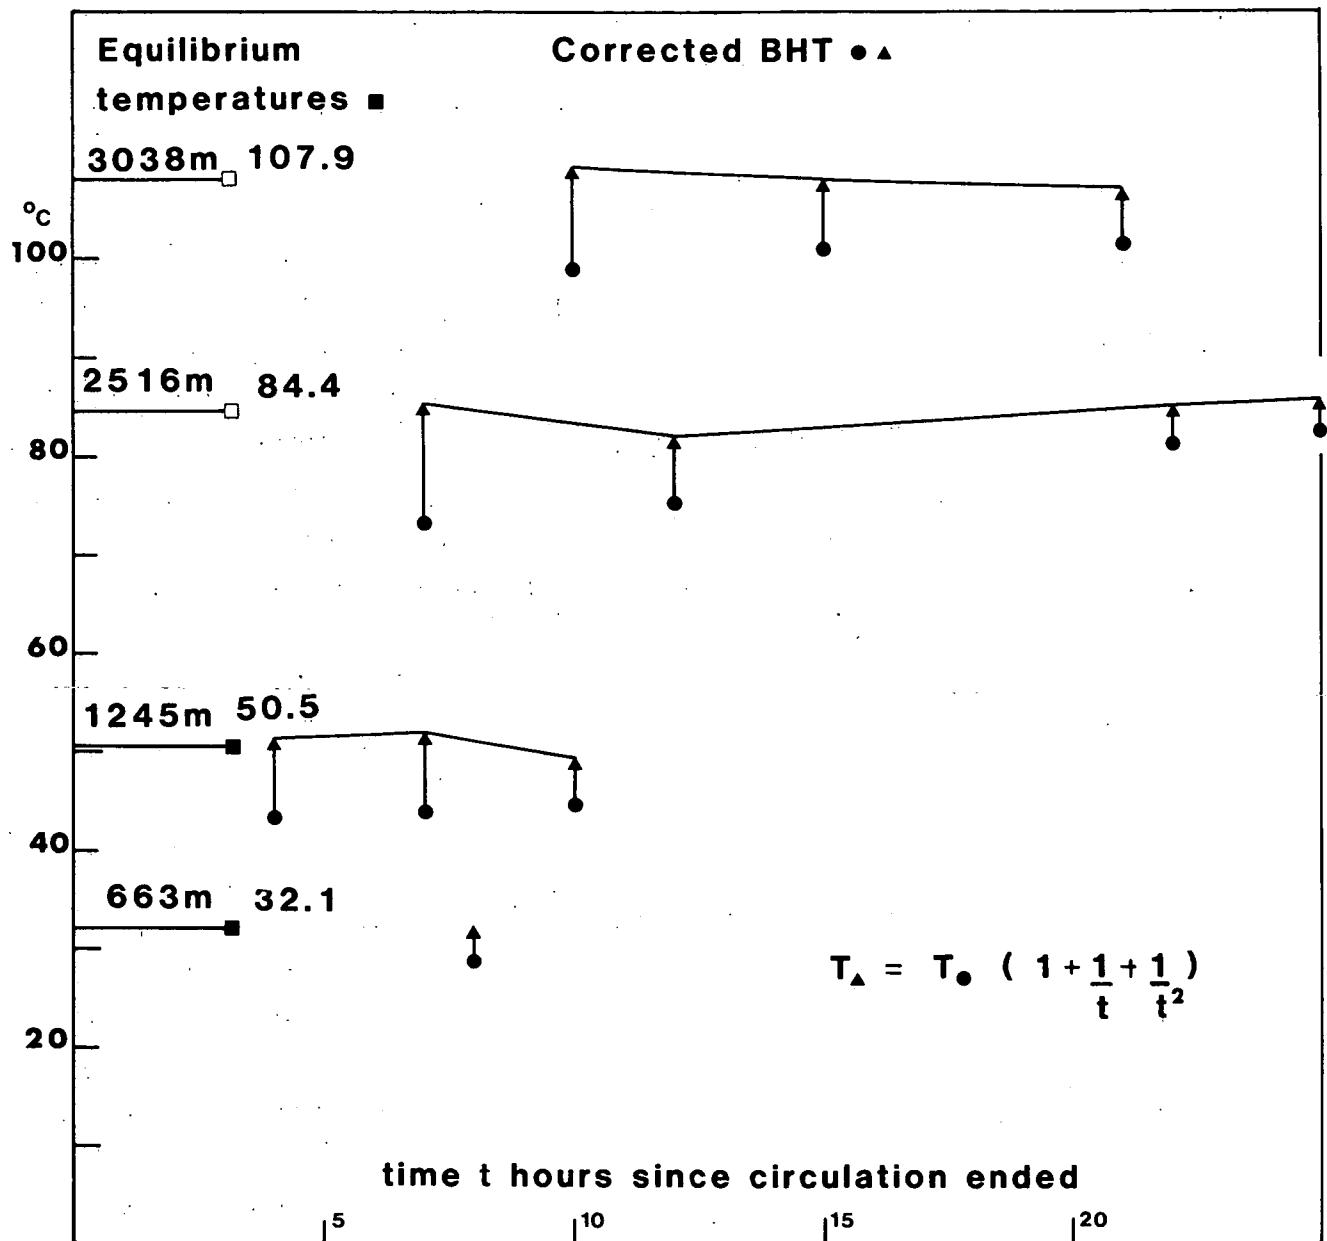

Figure 2 Winterborne Kingston borehole: Observed BHT data (shown by dots) have been corrected using the empirical formula shown to give the temperatures shown by triangles. Observed equilibrium temperatures are shown by squares.

Temperature gradients

Mean ground level temperatures for each borehole, were calculated as in the last revision, using a map of mean annual temperatures, corrected for elevation. When available, both rotary table (drill floor) and ground level elevations were recorded for the new boreholes, and mean geothermal gradients calculated relative to ground level.

Shallow temperature data alone are of little value for the prediction of deep sub-surface temperatures because the geothermal gradient at any site is a function of the local heat flow and conductivity, both of which can vary with depth. Over the sedimentary crust of the UK, thermal conductivity generally increases with depth, as the porosity decreases and the composition tends to become more siliceous. Although most of the temperature observations were made over sedimentary crust, this increase of conductivity is not clear in the plot of all observed temperatures against depth (Figure 3). The overall mean geothermal gradient is close to $26^{\circ}\text{C km}^{-1}$; the mean gradients for the data between surface and 1 km and between 2 and 3 km are 26.7 and $25.9^{\circ}\text{C km}^{-1}$ respectively. The main reason for this similarity is that few of the deeper boreholes penetrate Lower Palaeozoic sequences; most of the deeper hydrocarbon targets are within the Carboniferous strata which are usually associated with relatively low thermal conductivities.

Borehole geology

Sub-surface temperature data are more useful if a geological succession is also available for each observation. Convolution of the temperature data with a databank of thermal conductivity can then provide estimates of heat flow at each site. With this in mind, summary geological successions have, where available, been extracted for all new sites in the temperature catalogue. Of the new sites less than 30% do not have a geological summary. Furthermore, the geological information for the existing sites has also been expanded, such that 60% of the original sites now have geological data. Potentially the new catalogue allows an estimate of heat flow to be made at over 800 temperature sites. Most of the new temperature data is from commercial hydrocarbon wells, and as such the geological data is confidential and not listed in Table 1.

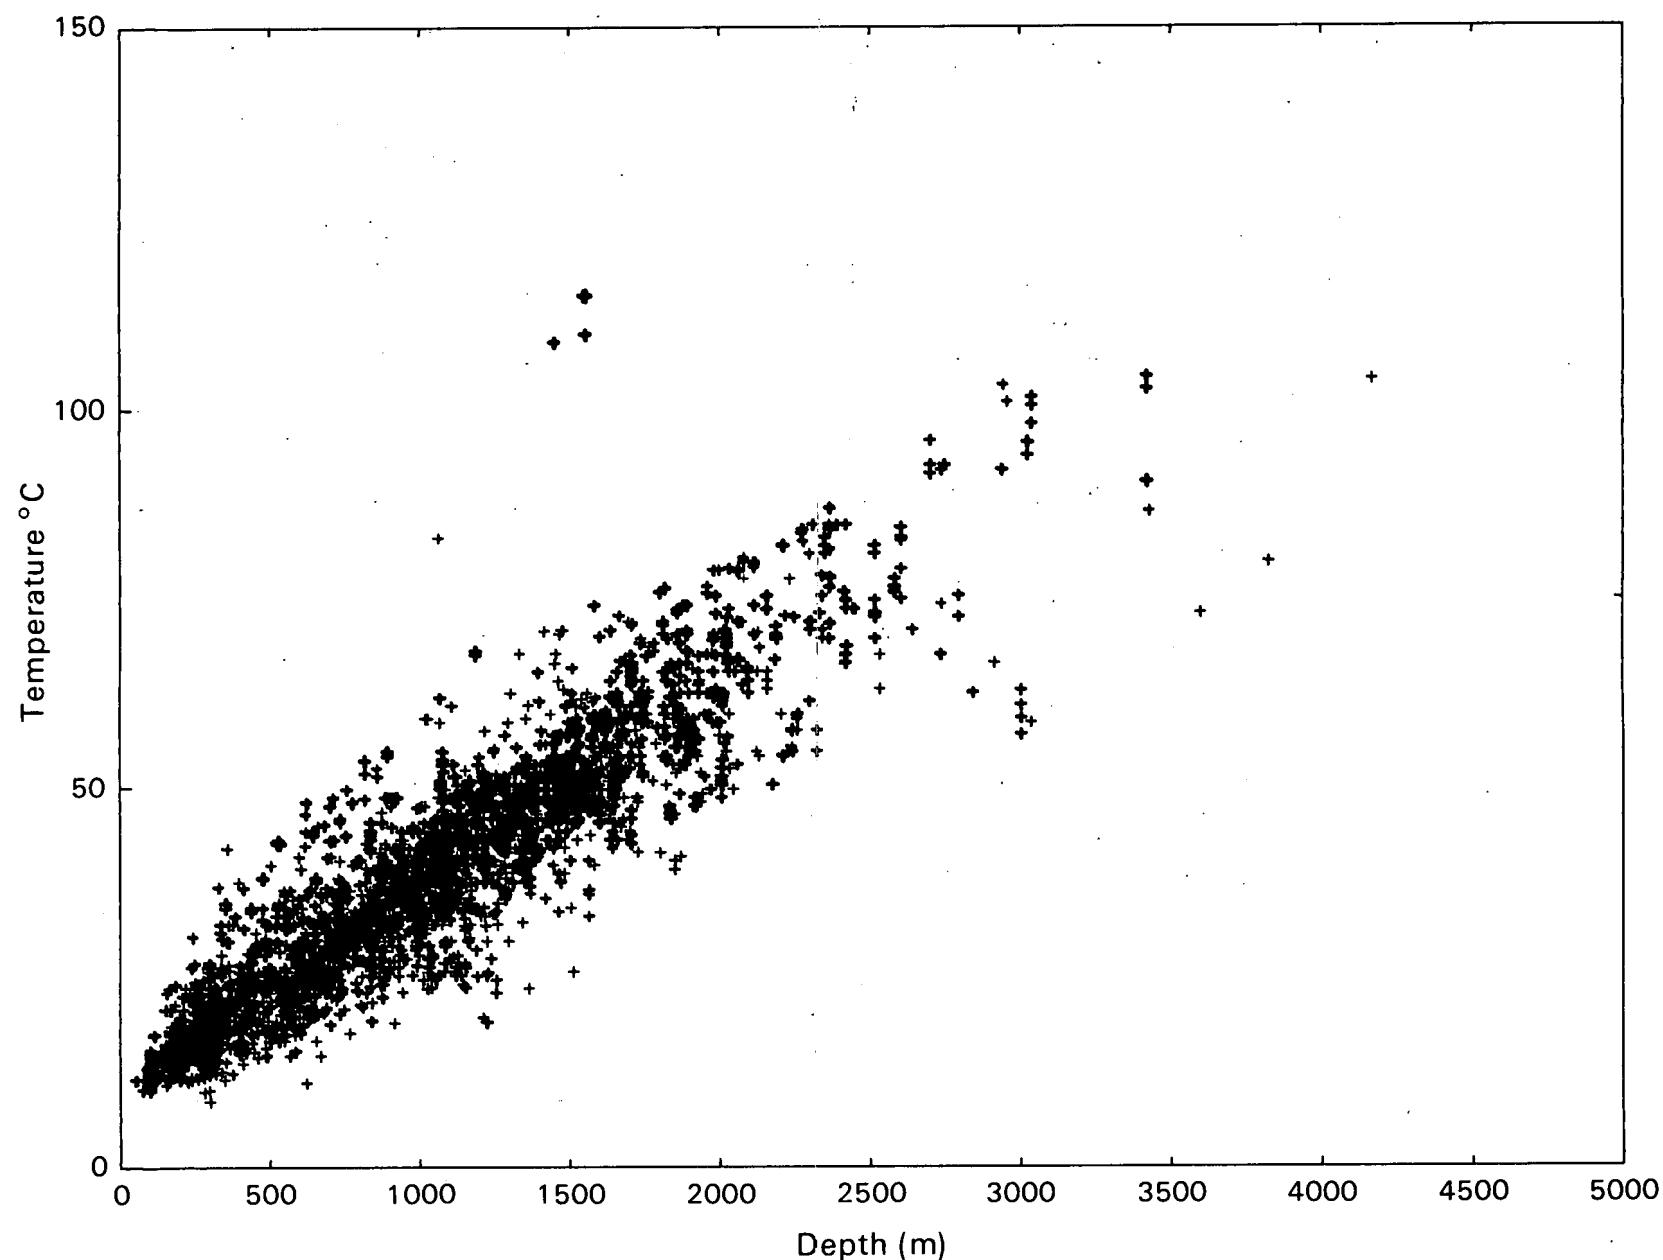

Figure 3 Relationship between depth and temperature in the UK. Uncorrected BHT data is plotted against depth. The least squares linear fit using 2620 points gives an average geothermal gradient of 25.6C km^{-1} .

3 Thermal conductivity

Thermal conductivity was not included in the last revision of the catalogue although the first revision included some conductivity data embedded in the heat flow table (Burley and Gale 1982). Because of the importance of rock thermal conductivity for sub-surface temperature modelling, a summary of the UK data is included below.

Rock thermal conductivity is largely determined by composition and porosity. In sedimentary rocks it ranges from about $1.5 \text{ W m}^{-1} \text{ K}^{-1}$ for clays to about $3.5 \text{ W m}^{-1} \text{ K}^{-1}$ for sandstones. Increasing porosity decreases thermal conductivity. Routine sampling at intervals of between 3 and 10 m within heat flow boreholes, provides the main source of thermal conductivity data. Prior to 1984, most heat flow boreholes outside south-west England were situated on the Upper Palaeozoic or Mesozoic sedimentary crust. Conductivity data from these boreholes, has allowed a general summary of the thermal conductivity of these formations to be made (Table 2.2 in Downing and Gray 1986). The mean thermal conductivity of over 1100 samples of Mesozoic strata for instance is $1.97 \text{ W m}^{-1} \text{ K}^{-1}$. Sampling of Lower Palaeozoic and older strata has been more restricted, although 7 of the 22 new heat flow boreholes (1984-87) have been on basement lithologies (see section 4).

Although thermal conductivity shows a strong dependence on temperature, resulting in a general increase in geothermal gradient with depth, this effect is usually overshadowed in the sedimentary crust, by the general increase of thermal conductivity with depth and age. In fact the new data have suggested higher mean thermal conductivities for basement lithologies and a consequent lowering of predicted temperatures at depth.

Downing and Gray (1986) quoted a mean thermal conductivity of $2.87 \text{ W m}^{-1} \text{ K}^{-1}$ for Lower Palaeozoic strata; whereas new data for selected sites on such formations give generally higher values. For example, the mean thermal conductivity of samples from the Selkirk heat flow borehole is $3.33 \text{ W m}^{-1} \text{ K}^{-1}$, while data from the Morley Quarry borehole in Precambrian basement give a mean thermal conductivity of over $4.1 \text{ W m}^{-1} \text{ K}^{-1}$.

In contrast, new data from the recent heat flow boreholes have confirmed the low thermal conductivity of Carboniferous strata. The mean of observations in the

Maryhill borehole in Glasgow is $2.40 \text{ W m}^{-1} \text{ K}^{-1}$ while for the Glenrothes borehole in Fife, the mean Carboniferous thermal conductivity is $2.34 \text{ W m}^{-1} \text{ K}^{-1}$. At the Harewood borehole near Leeds, the lower section of Carboniferous mudstone, from depths of 100 to 270m, has a mean thermal conductivity of only $1.20 \pm 0.15 \text{ W m}^{-1} \text{ K}^{-1}$, producing a local geothermal gradient of 56°C km^{-1} .

Where available, the arithmetic mean thermal conductivity for samples from each of the heat flow boreholes is included in the summary of heat flow data in Table 4. These data should be read in conjunction with the geological range of the sampled data, also indicated in Table 4. The numerical codes listed in the column 'geology' in Table 4 indicate the stratigraphic range of the borehole in terms of the map codes used on the published 1:625,000 Geological Map of Great Britain. For some boreholes, with a restricted geological range, this can give a reasonable guide to thermal conductivity, in other cases this is not so.

The mean basement conductivity for the 7 new heat flow boreholes on pre-Carboniferous rocks is $3.33 \text{ W m}^{-1} \text{ K}^{-1}$, while the mean of all the 1984-87 data (1199 measurements) is $2.79 \pm 1.0 \text{ W m}^{-1} \text{ K}^{-1}$. This is significantly different from the mean conductivity of $2.18 \pm 0.92 \text{ W m}^{-1} \text{ K}^{-1}$ for all the thermal conductivity data (1863 samples) for the 29 heat flow measurements made as part of the 1981-84 geothermal programme (Wheildon, Gebski and Thomas-Betts, 1985). A plot of all these data (3062 measurements) against depth (Figure 4) indicates the relatively shallow sampling of the data and also a skewed distribution; local concentrations of conductivity occur around 1.90 and $3.30 \text{ W m}^{-1} \text{ K}^{-1}$. This partly reflects the location of the sampling points ie. basement or sedimentary cover, but also the natural conductivity contrast between the two common lithologies sandstone and shale. Figure 5 shows the frequency distribution of the latest conductivity data compared to the earlier sample population.

Incidentally, if the mean UK geothermal gradient in the top few kilometres of the sedimentary crust (26°C km^{-1} , Figure 3) is combined with the mean UK heat flow (55 mW m^{-2} , see below), the expected mean thermal conductivity is $2.12 \text{ W m}^{-1} \text{ K}^{-1}$, similar to the mean of the earlier sample population. The higher mean conductivity for the recent heat flow boreholes indicates the sampling bias towards the basement lithologies. Conversely, since the temperature data are biased towards the cover sequences, a more realistic geothermal gradient for most of the exposed basement areas and the deep crust might be 16°C km^{-1} , based on a heat

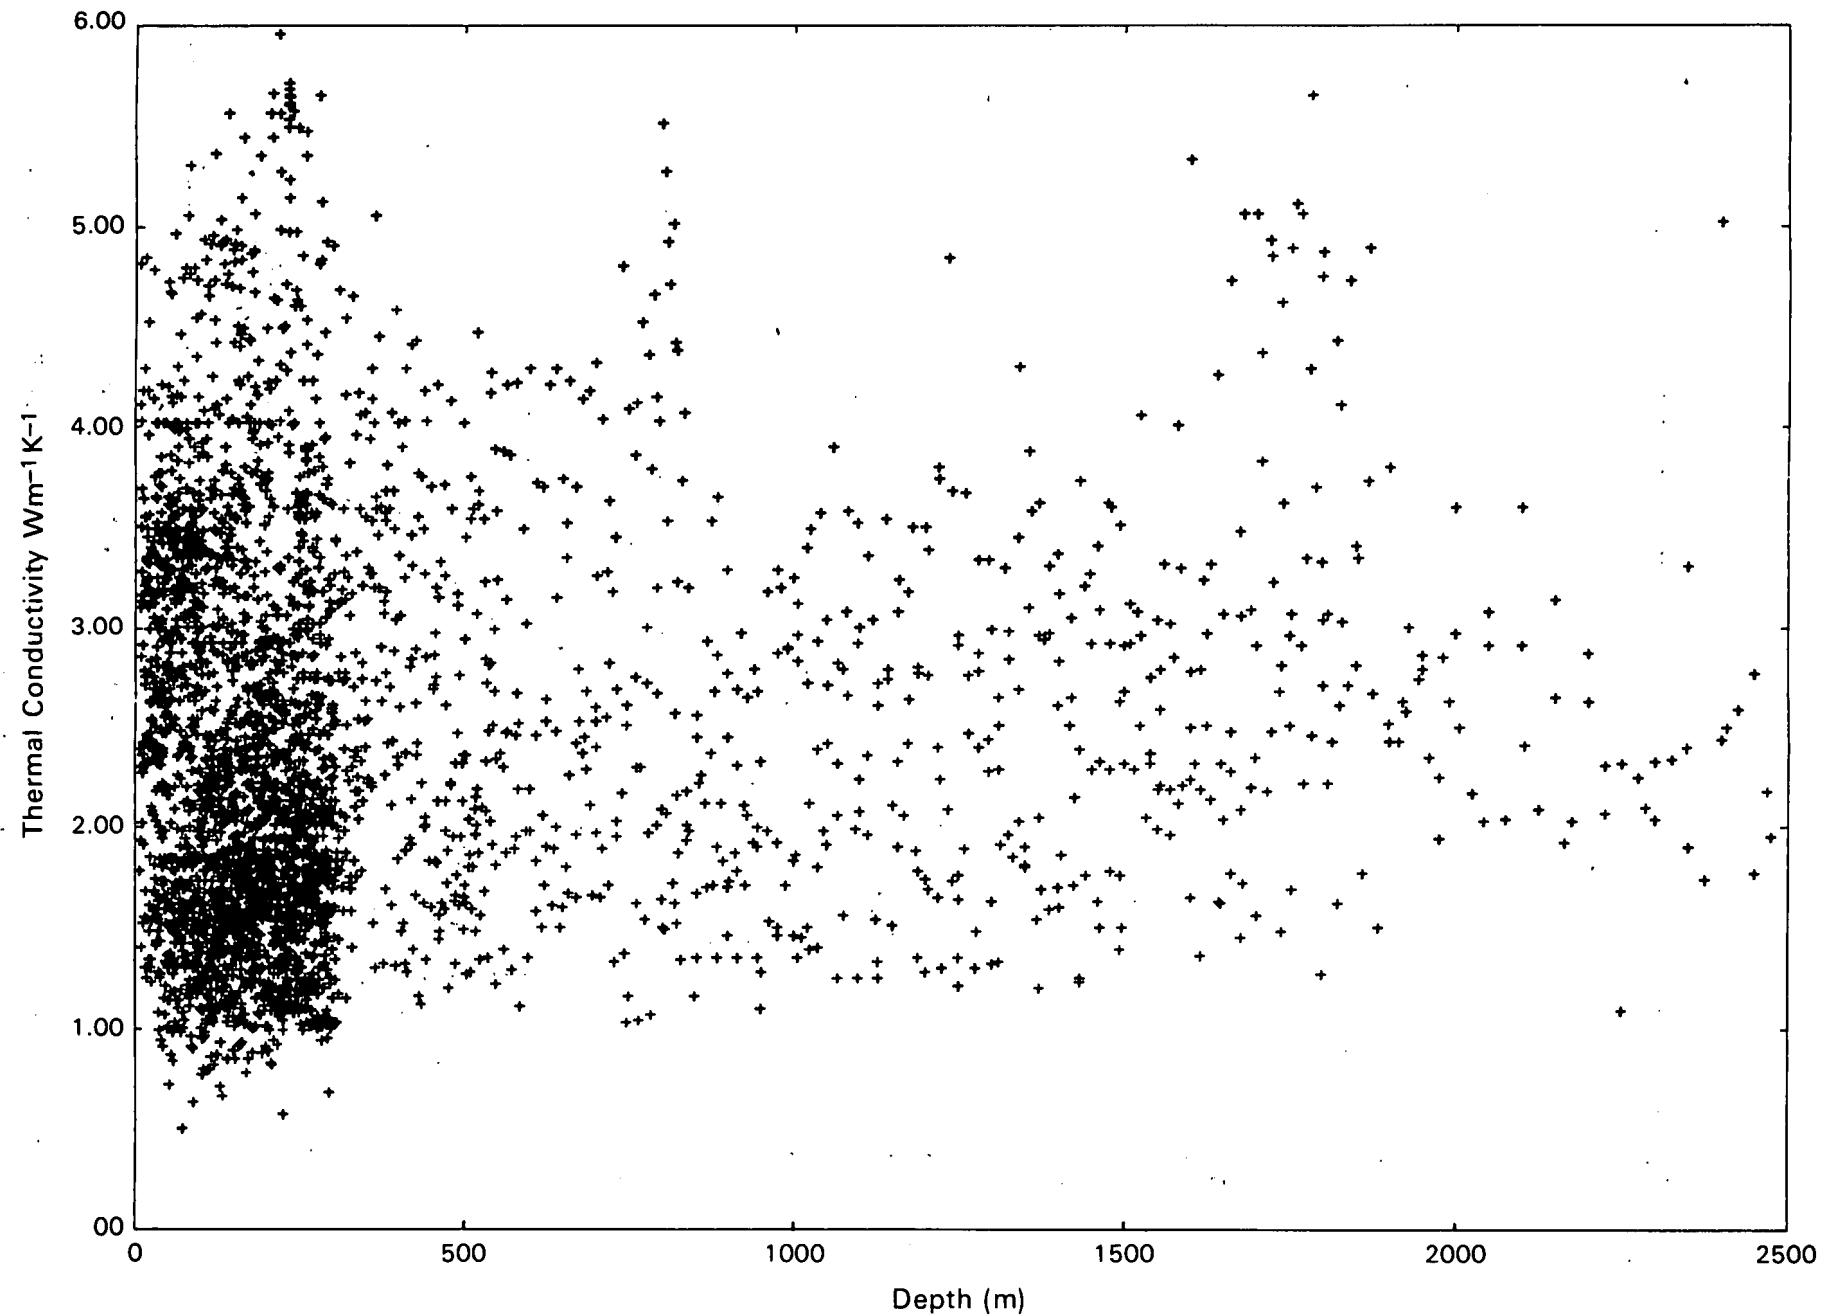

Figure 4 The distribution of thermal conductivity measurements with depth.

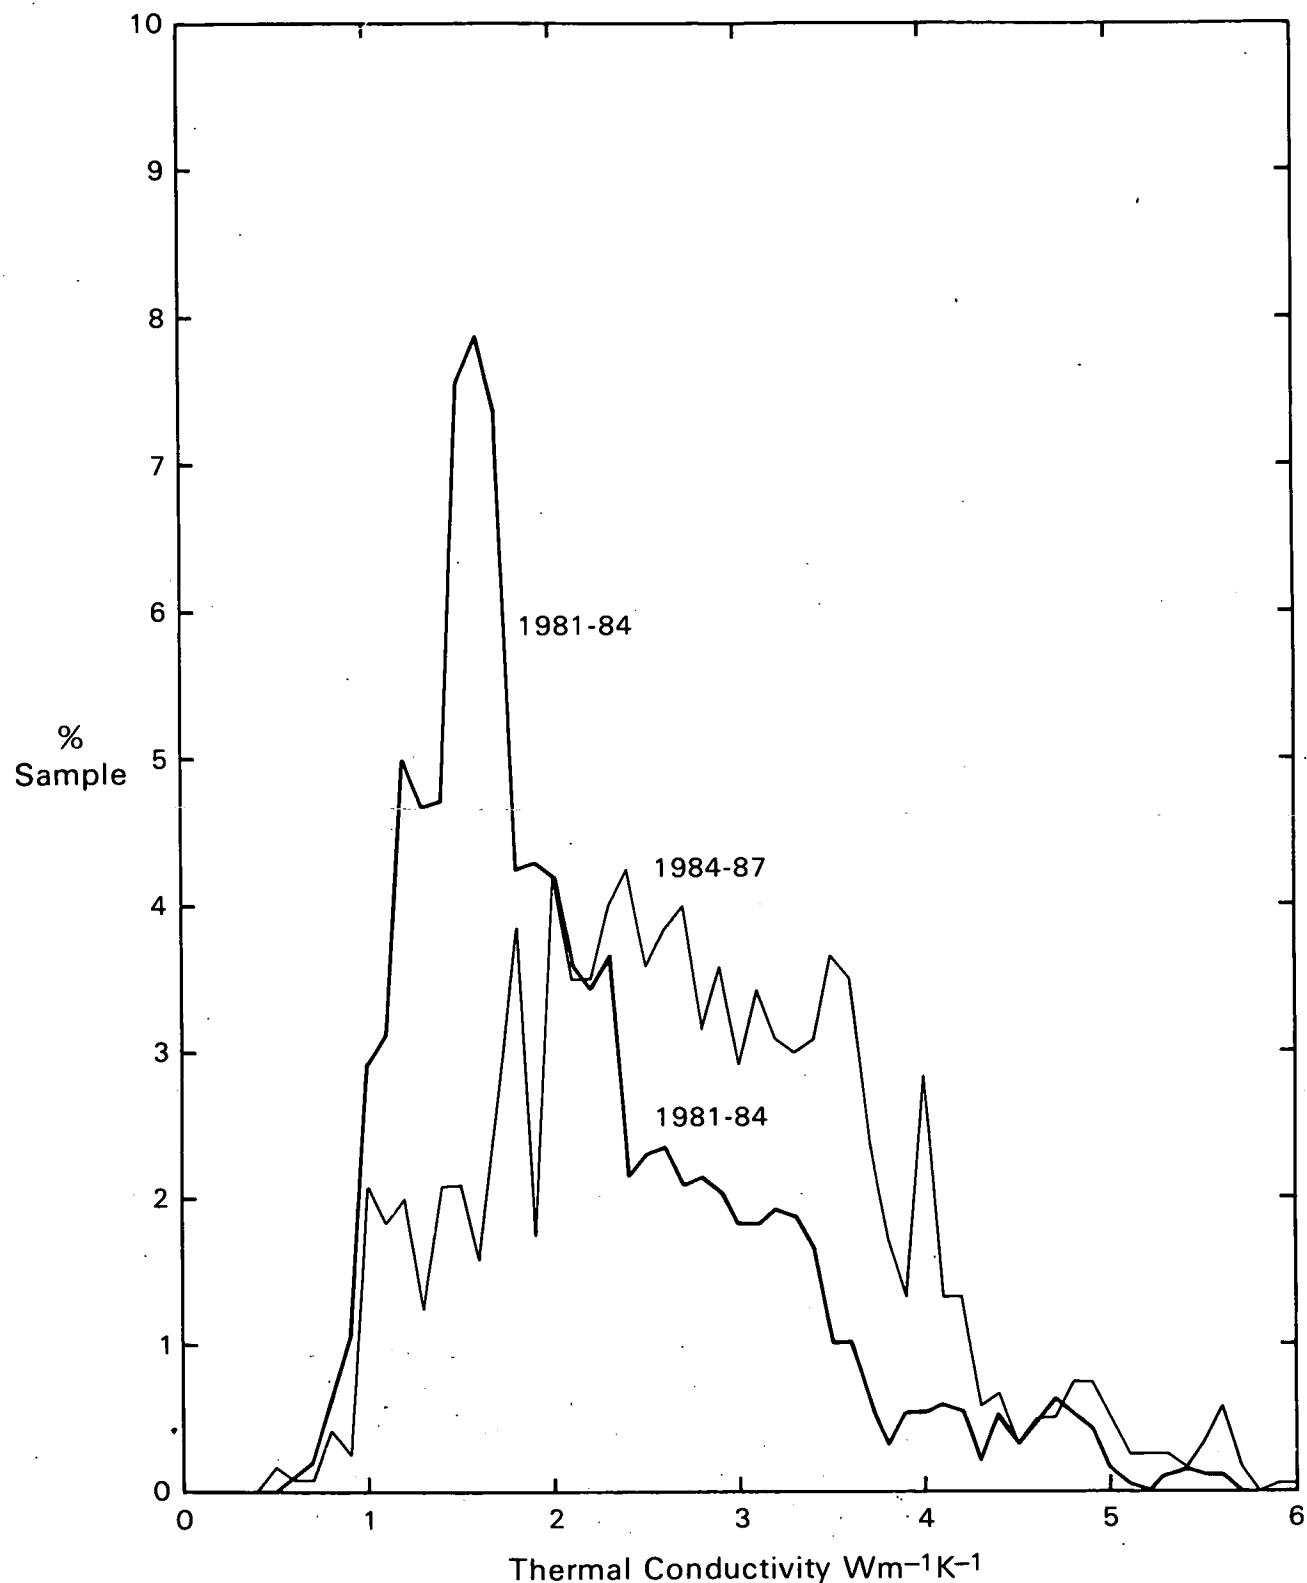

Figure 5 Frequency analysis of thermal conductivity data. The distribution of data collected during the 1981-87 Geothermal Programmes are shown.

flow of 55 mWm^{-2} and a thermal conductivity of $3.33 \text{ W m}^{-1} \text{ K}^{-1}$.

Table 3 is based on the summary given in Downing and Gray (1986), extended to include the Palaeozoic rocks where sampled. Because of the dependence of conductivity on porosity and lithology, mean values are difficult to assign for some of the stratigraphic units. Reliability should be gauged by the frequency of sampling and the likely lithological variation of the unit concerned.

Despite the recent new data from basement sites, the distribution of thermal conductivity with depth in the sedimentary crust, is one of the major uncertainties in temperature predictions to depths greater than about 2 km. In this respect deep temperature predictions are inherently more reliable in granites which have been shown, by geophysical interpretation, to extend to mid-crustal depths and be relatively homogeneous in terms of density and thermal conductivity.

4 Heat flow

Observations

The heat flow observations in the UK are presented in Table 4. New data collected since the last revision of the Catalogue are identified by lower case lettering of the borehole name. The data are in alphabetical order according to the British National Grid square and in numerical order by the geophysics reference number.

Table 4 gives basic location data, elevation, depth interval of the heat flow determinations and an indication of the temperature and thermal conductivity sampling. Arithmetic mean thermal conductivities and bottom-interval equilibrium temperatures are included where available. The two geology codes represent the stratigraphic interval of the borehole, using the numerical codes given on the 1:625,000 Geological Map of Great Britain. These codes can be used to give an indication of the conductivity of particular formations or to assess the potential for convection effects within the borehole. Identification of sources of the temperature and heat flow data is given in Section 6. The category of data in Table 4 follows the classification given in the last revision. Any climatic and topographic corrections included in the heat flow value, are given in the last two columns of Table 4.

The BGS 1984-87 geothermal programme has added 22 new heat flow observations to the existing dataset of 188 sites (Appendix 2 Downing and Gray 1986). All these new data have been collected by the Imperial College heat flow group under contract to BGS. In addition two heat flow measurements were made in the deep wells (RH11, RH12) at the Camborne School of Mines geothermal site at Rosemanowes. The criteria for siting the new heat flow boreholes included geophysical anomalies which might be caused by a buried granite (Market Weighton); basement terrains (Llanwrtyd Wells, Rhiw, Church Stretton); targets in the urban HDR study (Rowlands Gill) and gaps in the existing data distribution (Selkirk). In addition, two boreholes were specifically drilled to test the zone of high heat flow in the Bowland Forest area (Clitheroe 2, Wray). Eleven of the 22 new sites were in specially drilled holes 100-300m deep; the remaining observations were made in exploration boreholes at sites which satisfied one or more of the sampling criteria. Details of the individual sites are given in Gebski, Wheildon and Thomas-Betts (1987).

Heat production measurements were made at 4 boreholes on basement rocks in the English Midlands: - Morley Quarry ($0.7 \mu\text{W m}^{-3}$), Bardon Hill ($0.3 \mu\text{W m}^{-3}$), Church Stretton ($0.7 \mu\text{W m}^{-3}$) and Wyche ($1.6 \mu\text{W m}^{-3}$). In Morley Quarry, on Charnian rocks, measurements of radioactive U, Th and K appeared to show good correlation with downhole gamma ray spectrographic logs suggesting that leaching of U and Th from the borehole chippings was probably not significant.

Estimates of heat flow

Estimates of heat flow from 104 deep (>500m) boreholes were used in the compilation of the Geothermal Map of the UK (BGS 1985). The method involves combining BHT observations with a mean thermal resistance at each depth, derived from the borehole geology and a databank of mean thermal conductivity. Revision of the temperature catalogue and the databank of thermal conductivity has allowed heat flow estimates to be made at over 390 deep (>1000m) boreholes. These have been used in the compilation of the new heat flow map across southern England (Figure 6) and used in the calculation of deep temperatures (see front cover).

The heat flow map

The new heat flow map (Figure 6) shows some significant changes from that presented by Downing and Gray (1986) and shown on the published Geothermal Map both as a consequence of the strategic siting of the 22 new heat flow boreholes and the incorporation of the new estimates of heat flow from boreholes at least 1000 m deep.

In the East Midlands, the arcuate north-south zone of high heat flow (Gebski and others 1987) is based on poor quality measurements (class C,D) made in boreholes less than 600 m deep. Incorporation of the estimates of heat flow indicates the anomalous zone to be more localised and centred on the Eakring anticlinal structure.

Elsewhere, the new observations of low heat flow in Lancashire have removed the anomaly published on the Geothermal Map, while new measurements in central and mid-Wales have indicated a near average heat flow. The heat flow anomaly associated with the Weardale Granite has been confirmed and extended by the new measurement at Rowlands Gill (99 mWm^{-2}), above a shallow cupola of the granite, and by the observations made in the commercial boreholes at Newbiggin and Dufton.

Frequency analysis of the UK heat flow observations, indicates a bimodal distribution with a mean value of $68^{+26} \text{ mWm}^{-2}$. About 15% of the data is from sites above radioactive granites, although these rocks outcrop over less than 10% of the area. About 20% of the data is in south-west England. If these data are excluded the distribution becomes normal with a mean value close to $55^{+16} \text{ mWm}^{-2}$. This can be considered the mean value for the sedimentary crust of the UK. It should be emphasised that individual observations of heat flow in the sedimentary crust can only be considered as providing the apparent conductive heat flow, modified to some unquantifiable extent by convective flow. Local anomalies in the heat flow field can be useful indicators of hydrodynamics, but are generally only identified where data is especially concentrated.

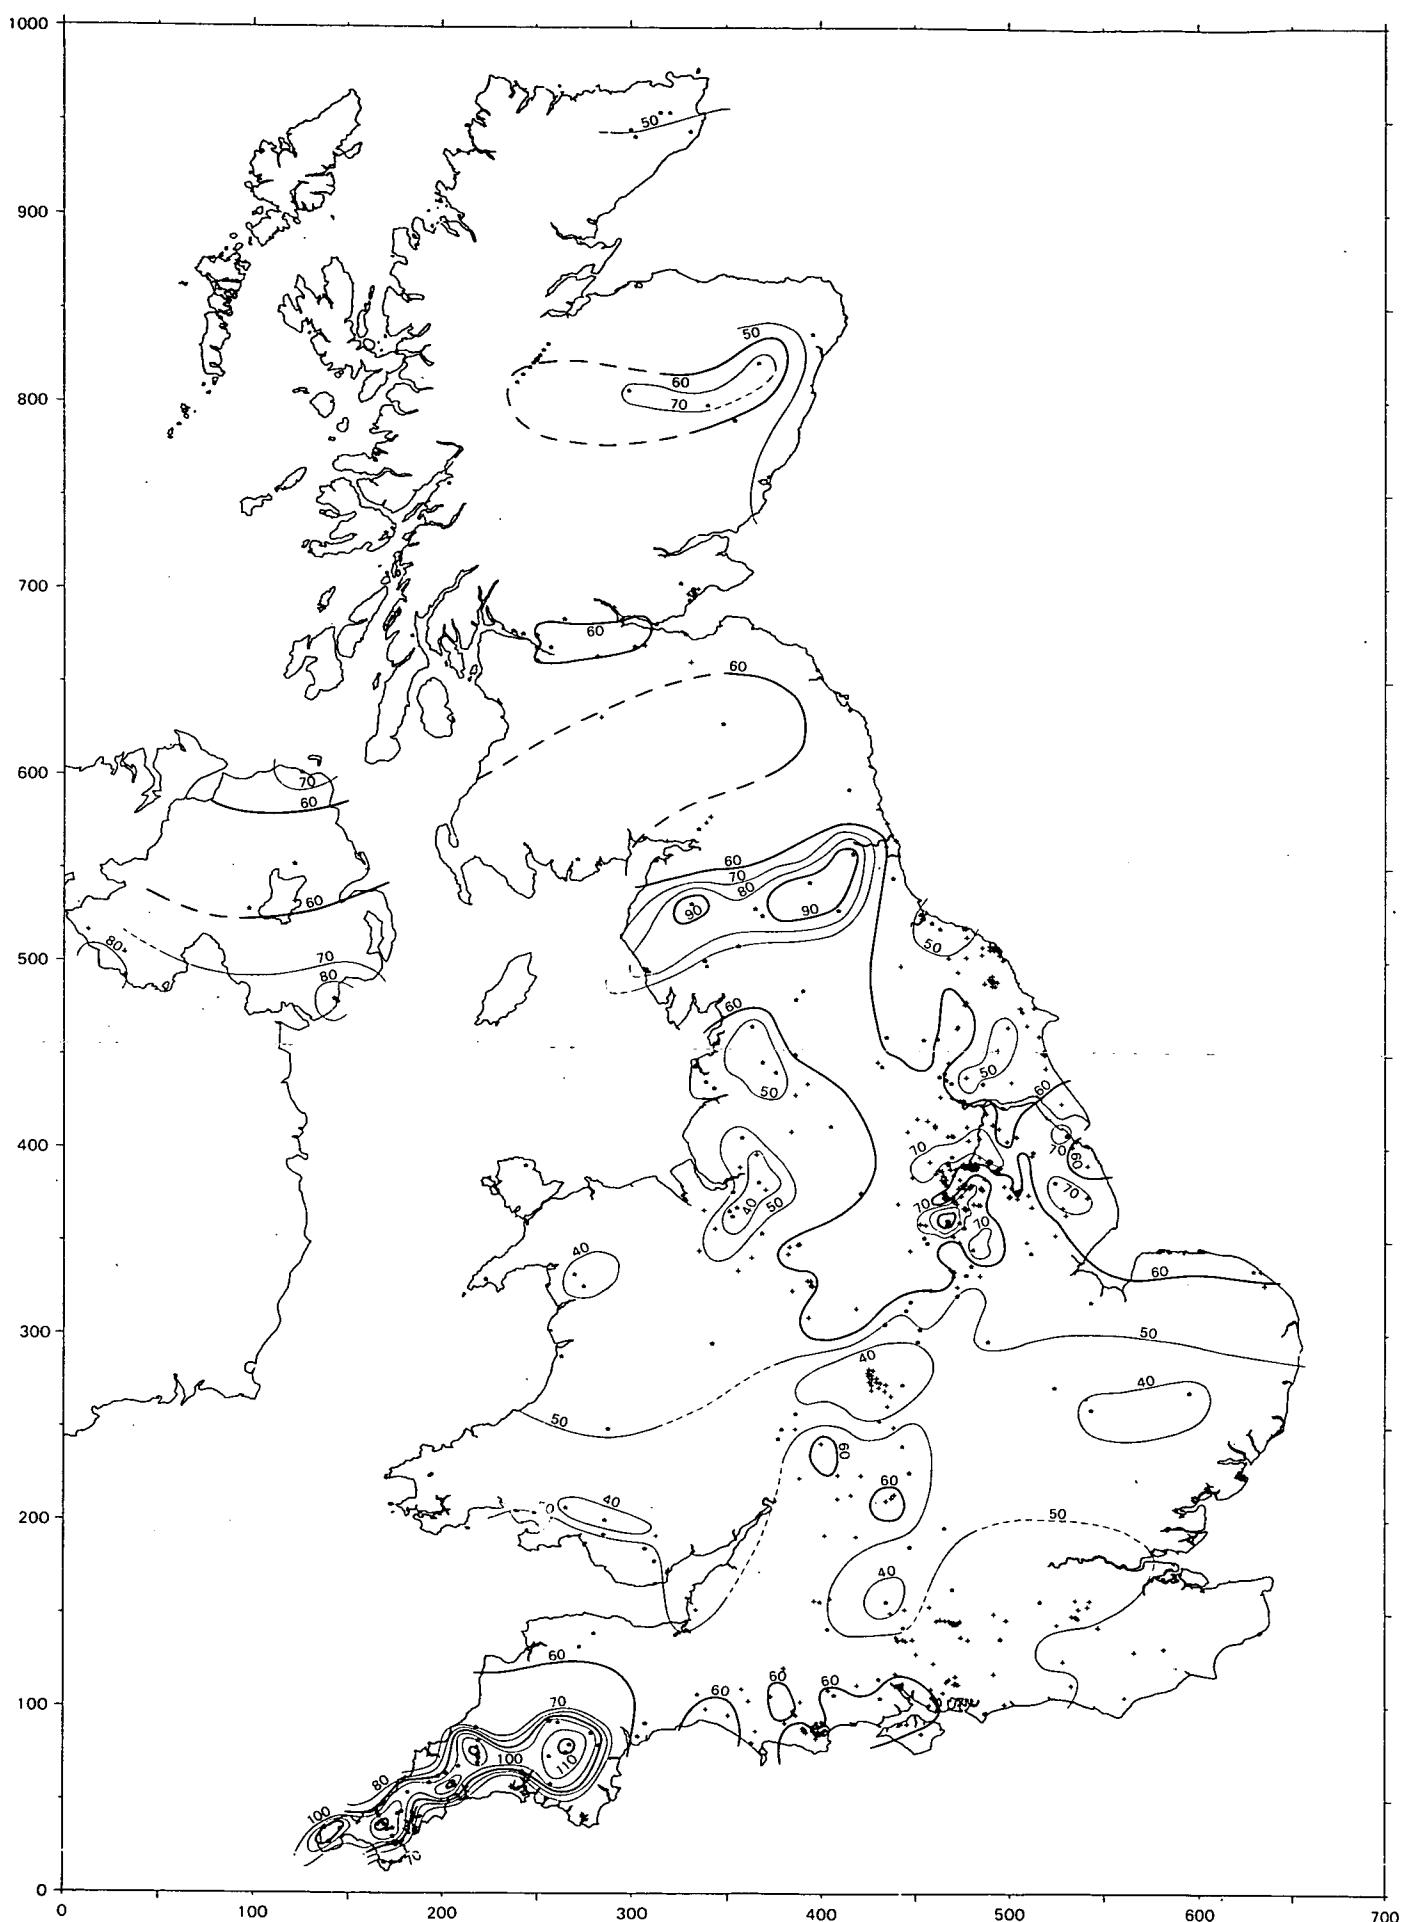

Figure 6 Heat flow map of the UK 1987. Contours are in mW m^{-2} . Locations of observed heat flow shown as asterisks, estimates of heat flow are shown as crosses.

5 Geochemical Data

The geochemical data are given in Table 5. Since the last Catalogue was issued a further 21 analyses have been incorporated. Most of these are of Carboniferous groundwaters collected from boreholes in the East Midlands' oilfields either by pumping or drill-stem tests (DST). Analyses of samples, including interstitial water samples, from isolated exploration and heat flow boreholes elsewhere in England and Scotland are also included, as well as one representative analysis of the Harrogate mineral springs and deep mine drainage waters from the Kent Coalfield.

Some of the oilfield samples had been stored for up to 18 months in glass bottles (seq. Nos. 85/130, 133, 139, 143, 147 and 149). This may have affected cation and SiO_2 values. In addition, many of the oilfield samples were originally in the form of oil-water emulsions, some of which required considerable solvent extraction to provide sufficient water for analysis. The nature of these samples, combined with the extractive process, has led, in a few cases, to poor ionic balances, possibly due to the presence of acetates. These factors should be borne in mind when using the geochemical data.

6 Sources of temperature and heat flow data

Data have been obtained from published literature, or from organisations for whom the measurements were made. In the case of bottom hole temperatures (BHT), the authors normally compiled the data from information given on geophysical borehole logs, and the source given is the organisation for whom the logs were run. The following abbreviations are used in Tables 1, 2 and 4 (the inclusion of a year, as in Benfield, 1939, indicates a reference):

Table 1 UK Temperature Data Third Revision 1984-1987

Table 2 Summary of UK Temperature Data Third Revision 1987

Explanation of column headings and abbreviations

RG No.	: Geophysics borehole reference number. Letters indicate the 100km British National Grid square. Data are ordered according to this field.
BGS No.	: BGS borehole reference number where known.
BNG-E, BNG-N	: British National Grid reference, Easting and Northing to 10m. In Northern Ireland the geographic co-ordinates have been transformed to give the BNG reference for plotting purposes.
Data	: Other data given in the Catalogue. HF indicates a heat flow site, G geochemical data.
Oper	: Source of the data, or drill operator. A list of sources is given in Section 6.
yr	: Year in which measurements were made or reported.
elev	: Ground level elevation in metres above Ordnance Datum.
To	: Mean annual ground level temperature in degrees Celsius.
nT	: The number of temperature observations made in this borehole.
depth	: Vertical depth in metres below ground level.
Temp, Tz	: Observed temperature in degrees Celsius. In Table 2 the highest observed temperature at each site (Tz) is the corrected value where available.
grad	: Calculated average temperature gradient in degrees Celsius per kilometre from depth of observation to ground level.
Obs	: Type of temperature observation. The following abbreviations are used. BHT Bottom hole temperature EST Estimated temperature LOG Log temperature MWT Mine water temperature CFM Coal field measurement DST Drill stem test PRO Production test VST Virgin strata temperature EQM Equilibrium temperature HOR Calculated equilibrium temperature by the Horner-plot method (see below)

time : time between the end of circulation of drilling fluid and the measurement of temperature, in hours (H), days (D), months (M) or years

ctemp : Corrected temperature gradient in degrees Celsius for post-circulation times greater than 5 hours, using the method described in Section 2 for new data (Table 1).

cgrad : Corrected temperature gradient.

Table 1 Horner-plot equilibrium formation temperatures

Equilibrium formation temperatures can be estimated from a sequence of BHT observations at the same depth if the time of mud circulation (t_c) at that depth is known as well as the time since circulation ended (t) for each BHT. A plot of observed BHT against $t/(t_c+t)$ on log-normal paper should give a straight line, the temperature at the value $t/(t_c+t)=1$ being the equilibrium formation temperature.

For the data listed in Table 1 a Horner-plot analysis has been made for BHT observations which satisfy the following criteria:

- at least 3 BHT have been recorded over a depth range not greater than 10m
- these BHT data show a positive correlation with the times since circulation ended.

A constant circulation time of 10 hours has been assumed for all depths in all boreholes. For each site, the Horner equilibrium temperatures are listed at the end of the observed temperature data and identified with the code 'HOR' in the observations column. As a guide to data consistency, the correlation coefficient of the Horner-plot line is given to one decimal place in the time column.

nk :number of samples

cond :thermal conductivity W/m/K

se :standard error

Code :geological code number used on 1:625000 geological maps

Lithology: SMST, sandy mudstone; MDST, mudstone; LMST, limestone
SDST, sandstone; SLST, siltstone; SLCL, silty clay;
SLMD, silty mudstone; HALI, halite; ANHY, anhydrite;
SLAT, slate.

Table 4 UK Heat Flow Data

Explanation of column headings and abbreviations

Basic reference and location headings are described for Tables 1 and 2. Lower case lettering for the borehole name indicates data acquired since the last revision.

elev	: ground elevation in metres above Ordnance Datum
depths	: depth interval used for determination of the heat flow
nk	: number of thermal conductivity measurements made in this borehole
cond	: arithmetic mean thermal conductivity for the borehole in $\text{W m}^{-1} \text{K}^{-1}$
nT	: number of temperature observations made in the borehole
temp	: measured temperature at the maximum depth
geology	: approximate stratigraphic interval of the heat flow borehole. The two codes represent the upper and lower stratigraphic units using the codes from the 1:625,000 Geological Map of Great Britain
hf	: observed heat flow in mW m^{-2}
source	: source of the data. Identification is given in Section 6. The category of the data (A-D, L) is as described in the Second revision
clim	: any palaeoclimate correction included in the heat flow in mW m^{-2}
topo	: any topographic correction included in the heat flow in mW m^{-2}

Table 5 Geochemical Data

Explanation of certain column headings and abbreviations

Seq. No.	: BGS hydrochemical data file number.
Locality	: Name of borehole/locality, abbreviated site description.
NGR	: British National Grid Reference, to 10 metres where known.
Depth Well	: In the case of a borehole this represents the total drilled depth in metres.
Depth Sample	: Depth in metres, of sample below ground level.
Form	: Formation from which the water sample was derived, where known. Letters refer to the BGS lithostratigraphical code. A list of codes used, in chronological order, is to be found at the end of this note.
Date	: Day, month and year in which chemical analysis was carried out. 18 06 70 refers to 18 June 1970.
Type	: Code refers to sample source as follows: 02 - spring 10 - pumped sample 13 - underground mine drainage 17 - interstitial 27 - drill-stem test
Temp	: Water temperature measured either on discharge at surface, in underground workings, or by downhole temperature probe, in degrees Centigrade.
pH	: pH (undifferentiated) either measured in situ or on laboratory sample.
Chemical analysis:	Concentration of Na, K, Ca, Mg, HCO ₃ , SO ₄ , Cl and Si, where measured, in milligrams per litre.
TDS	: Total dissolved solids. This value is a sum of the major component ions listed. If no value of an ion is available, except for Si, then the TDS value is not calculated.
