INTRODUCTION

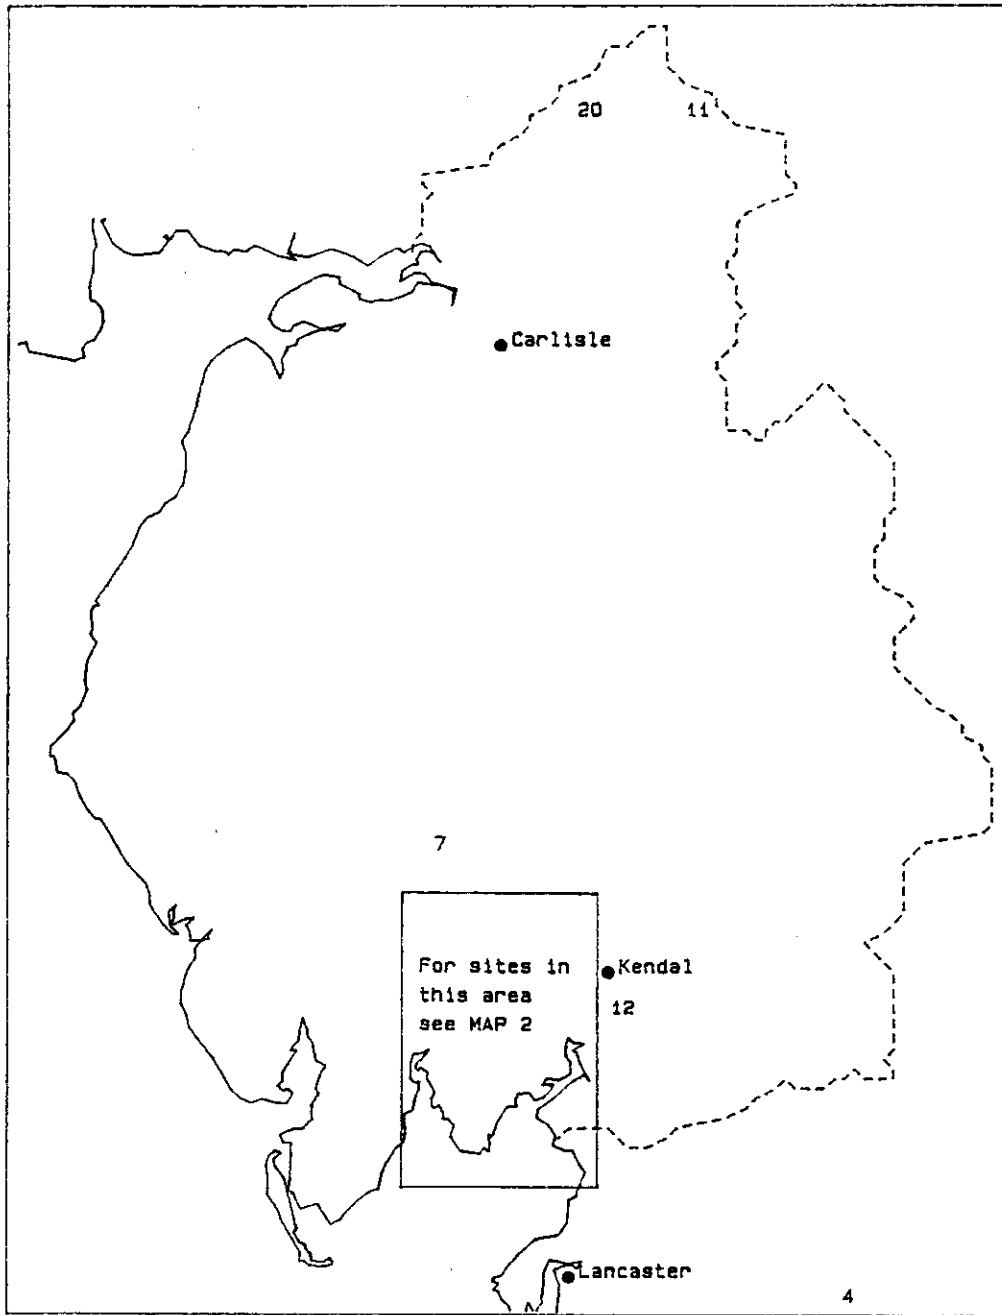

Merlewood was the first research station to be set up by the Nature Conservancy in the early 1950s in order to provide laboratories for the moorland and woodland soils programmes. Significant in the choice of location was the proximity of the proposed Reserve at Roudsea Wood, the Meathop Moss Reserve, the experimental Reserve at Moor House and a number of other sites of special interest. The results of research work at these sites has been published in journals, conference proceedings and books.

A bibliography of research publications relating to Moor House National Nature Reserve has already been produced¹, and the results of studies there under the International Biological Programme (IBP) have also appeared².

This bibliography lists the publications which have resulted from research at the woodland and forest sites, and in the case of Meathop Wood, which was the main IBP site in the UK for studying the productivity of woodlands, includes work by scientists from universities and other institutes. Most of the references should be readily available through normal library channels, but in case of difficulty, please apply to the Librarian at Merlewood.

BIBLIOGRAPHY

Roudsea Wood (SD 330820)

Roudsea Wood, declared a National Nature Reserve in 1955, is one of the most varied woodlands in the British Isles. It lies in the south of the English Lake District and is about five miles west of Grange-over-Sands. The main part of the wood is situated on two parallel ridges, one of Carboniferous limestone, the other of Silurian slate. The limestone ridge supports coppiced ash-oak woodland with the oak being mainly pedunculate; the slate ridge, on the other hand, carries a contrasting sessile oak-wood, with birch.

Research effort at Roudsea was concentrated initially on the biological and chemical processes occurring in the soil and litter, but attention was also given to the problem of poor natural regeneration of the oak-wood, and its defoliation by Tortrix viridana caterpillars. The decomposition studies were extended to include work on the fungal succession on decaying bracken.

Resistance in oak (Quercus spp.) to defoliation by Tortrix viridana L. in Roudsea Wood National Nature Reserve.
Ann. appl. Biol., 50, 431-442.
25. SYKES, J.M. & BARR, C.J. 1973.
Dry weight and mineral composition estimates for 15-year-old mixed hardwood coppice in Roudsea Wood. (Merlewood research and development paper no. 50).
Grange-over-Sands: Nature Conservancy.
26. SYKES, J.M., HORRILL, A.D. & MOUNTFORD, M.D. 1983.
Use of visual cover assessments as quantitative estimators of some British woodland taxa.
J. Ecol., 71, 437-450.
27. TWINN, D.C. 1962.
The extraction of free-living nematodes from forest soil and litter. In: Progress in soil zoology, edited by P.W. Murphy, 261-267.
London: Butterworths.
28. WAID, J.S., CAPSTICK, C.K. & TWINN, D.C. 1957.
A quantitative method of estimating fungal infections of natural populations of free-living nematodes.
Pedologie, 7, 159-161.

Meathop Wood (SD 436795)

In 1963, the International Biological Programme was initiated as a cooperative effort on the part of scientists throughout the world to study the basic processes of biological productivity. The main UK site for studying the productivity of woodlands was Meathop Wood, about two miles from Merlewood near the shore of Morecambe Bay. It is situated on an outcrop of Carboniferous limestone, and is a coppiced wood, with oak, ash, birch and sycamore standards dominating the canopy and an understorey of hazel.

Research at Meathop was concerned with the production and standing crop of the trees and ground flora, the amount of energy and nutrient yielding material entering the plant-soil ecosystem, the types and biomass of the organisms present, and the relative contribution of the different groups of soil organisms to the processes of decomposition.
