# Hydrological Summary for the United Kingdom 

#### Abstract

General Overall, March was a mild, sunny and - after a very wet first week - a generally dry month punctuated by several notably cool and windy interludes. Winter half-year (Oct-Mar) rainfall totals were exceptionally high across much of the UK; for some parts of southern Britain March was the first month with below average rainfall since last July. Reservoir drawdown for flood alleviation purposes was common during the first week of March but, entering April, overall stocks for England and Wales remained above the monthly average, with most impoundments exceeding 90\% of capacity (Colliford is an exception). Flood alerts were widespread early in the month but steep river flow recessions became established thereafter; seasonally low flows were reported for many responsive rivers by early April. Groundwater levels in March, responding to the heavy late-winter recharge, were considerably above the seasonal average in most aquifer outcrop areas. Correspondingly, the water resources outlook is very encouraging but a particularly notable hydrological characteristic of March was the rapid growth in soil moisture deficits, raising the possibility of an early termination to the 2006/07 aquifer recharge season in eastern and southern England.

## Rainfall

March began in a very unsettled vein with damaging gales, in the west particularly and substantial rainfall over the first 6-8 days (Torquay 33 mm on the $4^{\text {th }}$, Keswick 48 mm on the $6^{\text {th }}$ ). Notwithstanding incursions of Arctic airmasses (with significant snowfall on high ground on the $18 / 19^{\text {th }}$ and considerable transport disruption), high pressure dominated synoptic patterns thereafter. A few local thunderstorms (e.g. west of London) were reported around month-end but in many areas a notable dry spell extended well into April. From March $6^{\text {th }}$ accumulated rainfall totals for some central southern locations remained below 10 mm for over 38 days; the longest such sequence since early 1998 in Wallingford. Nonetheless, March rainfall totals were in the normal range, typically $80-120 \%$ average, across most of the country. Western Scotland was, again, particularly wet (some localities registering $>140 \%$ ) whilst totals fell below $40 \%$ in a few parts of north-east England. The recent dry spell makes for a dramatic contrast with longer term rainfall accumulations. Jan-Mar rainfall totals appreciably exceeded the average in all regions; more notably, winter half-year totals are exceptional over wide areas. The provisional Oct-Mar rainfall total for the UK is the highest on record - in a series from 1914. This primarily reflects exceptional precipitation totals across Scotland which exceeded its previous Oct-Mar maxima by a wide margin (with anomalies $>50 \%$ in some northern and western area). 12-month rainfall accumulations also exceed the average in all regions, and for Scotland a new 12 -month maximum (for any start month) has been established (in a 93-yr series).

## River flow

In most areas, March witnessed a dramatic change in river flows through the month. In the first week modest floodplain inundations were very widespread (on the $7^{\text {th }}$ the Wye registered its highest March daily flow for 60 years) but flows in many responsive rivers declined very briskly thereafter. This hydrological transformation is exemplified by the Forth which exceeded bankfull in early March but four weeks later established new early-April daily minima. By contrast, baseflows in some spring-fed streams continued to increase, resulting in notable March runoff totals - the highest in a 44 -yr record for the Coln
(in the Cotswolds). Flows were very healthy in many groundwater-fed southern rivers also (which was beneficial for the replenishment of a number of pumpedstorage reservoirs). Northern England aside, most March runoff totals were above average, notably so for some western catchments (e.g. the Ewe and Warleggan). More exceptional however were the winter half-year runoff accumulations. Most Oct-Mar runoff totals were well above average; many were outstanding. The Tay, Cynon and Dart registered their highest 6-month runoff totals for any start month in series of around 50 years. Many other index rivers draining impermeable catchments, reported exceptionally high winter half-year runoff totals. Given the magnitude of the winter runoff, it is notable that very few extreme flood events were reported.

## Groundwater

Rainfall across most aquifer outcrop areas during March was concentrated in the first week when soils remained close to saturation; it was therefore very hydrologically effective. The March recharge helped to reinforce the recoveries in groundwater levels over the 2006/07 winter. In the southern Chalk, March levels were generally well above average and, commonly, the highest for at least four years. In the slower-responding Chalk of the Chilterns levels returned to the seasonal mean for the first time since late 2003 but levels are still below average in a few Lower Greensand outcrops (e.g on the Isle of Wight). Throughout the limestone outcrops March levels were generally well within the normal range but the Permo-Triassic sandstones continue to present a very spatially variable picture. March levels were very healthy in most northern outcrops, and in the South West but still depressed in many very slow-responding Midland outcrops. Levels are also relatively low in a few minor aquifers (eg. the Suffolk Crag). Overall groundwater resources are very healthy and a dramatic contrast to the early spring of 2006 . However, during the dry latter half of March seasonal recessions became established in the more responsive groundwater units. With desiccating winds contributing to the brisk rise in soil moisture deficits (which continued well into April), an early end to the 2006/07 recharge season, in the east particularly, is an increasing possibility.

## Rainfall accumulations and return period estimates

## Rainfall... Rainfall . . .

## Key

Abore Normal range

October 2006 - March 2007
April 2006 - March 2007

## Rainfall accumulation map

The winter half-year was notably wet across almost the entire country and for a few southern areas the Oct-Mar total approached the combined totals for 2004/05 and 2005/06. In the 12-month timeframe 10-11Scotland was exceptionally wet - much of western Scotland registered its highest April-March rainfall on record - but, in England, the South West Region only marginally exceeded the 1961-90 average.

## River flow . . . River flow

## River flows

*Comparisons based on percentage flows alone can be misleading. A given percentage flow can represent extreme drought conditions in permeable catchments where flow patterns are relatively stable but be well within the normal range in impermeable catchments where the natural variation in flows is much greater. Note: the period of record on which these percentages are based varies from station to station. Percentages may be omitted where flows are under review.

## River flow . . . River flow

## River flow hydrographs

The river flow hydrographs show the daily mean flows together with the maximum and minimum daily flows prior to April 2006 (shown by the shaded areas). Daily flows falling outside the maximum/minimum range are indicated where the bold trace enters the shaded areas.

## River flow . . . River flow

Notable runoff accumulations (a) October 2006 - March 2007, (b) April 2006 - March 2007

## Groundwater . . . Groundwater

Groundwater levels normally rise and fall with the seasons, reaching a peak in the spring following replenishment through the winter (when evaporation losses are low and soil moist). They decline through the summer and early autumn. This seasonal variation is much reduced when the aquifer is confined below overlying impermeable strata. The monthly mean and the highest and lowest levels recorded for each month are displayed in a similar style to the river flow hydrographs. Note that most groundwater levels are not measured continuously - the latest recorded levels are listed overleaf.

## Groundwater...Groundwater

## Groundwater levels - March 2007

The rankings are based on a comparison between the average level in the featured month (but often only single readings are available) and the average level in each corresponding month on record. They need to be interpreted with caution especially when groundwater levels are changing rapidly or when comparing wells with very different periods of record. Rankings may be omitted where they are considered misleading.
Notes: i. The outcrop areas are coloured according to British Geological Survey conventions.
ii. Yew Tree Farm levels are now received quarterly.
iii. Data for Nuttalls Farm are currently under review.

| () figures in parentheses relate to gross storage |  | - denotes reservoir groups |  | +excludes Lough Neagh |  |  |  | *last occurrence |  |  |

Details of the individual reservoirs in each of the groupings listed above are available on request. The percentages given in the Average and Minimum storage columns relate to the 1988-2006 period except for West of Scotland and Northern Ireland where data commence in the mid-1990's. In some gravity-fed reservoirs (e.g. Clywedog) stocks are kept below capacity during the winter to provide scope for flood attenuation purposes.

## Location map . . . Location map

# National Hydrological Monitoring Programme 

The National Hydrological Monitoring Programme (NHMP) was instigated in 1988 and is undertaken jointly by the Centre for Ecology and Hydrology Wallingford (formerly the Institute of Hydrology - IH) and the British Geological Survey (BGS). Financial support for the production of the monthly Hydrological Summaries is provided by the Department for Environment, Food and Rural Affairs (Defra), the Environment Agency (EA), the Scottish Environment Protection Agency (SEPA), the Rivers Agency (RA) in Northern Ireland, and the Office of Water Services (OFWAT).

## Data Sources

River flow and groundwater level data are provided by the Environment Agency, the Environment Agency Wales, the Scottish Environment Protection Agency and, for Northern Ireland, the Rivers Agency and the Department of the Environment (NI). In all cases the data are subject to revision following validation (flood and drought data in particular may be subject to significant revision).
Reservoir level information is provided by the Water Service Companies, the EA, Scottish Water and the Northern Ireland Water Service.

The National River Flow Archive (maintained by CEH Wallingford) and the National Groundwater Level Archive (maintained by BGS) provide the historical perspective within which to examine contemporary hydrological conditions.

## Rainfall

Most rainfall data are provided by the Met Office (see opposite). To allow better spatial differentiation the rainfall data for Britain are presented for the regional divisions of the precursor organisations of the EA and SEPA. Following the discontinuation of the Met Office's CARP system in July 1998, the areal rainfall figures have been derived using several procedures, including initial estimates based on MORECS*. Recent figures have been produced by the Met Office, National Climate Information Centre (NCIC), using a technique similar to CARP. A significant number of additional monthly raingauge totals are provided by the EA and SEPA to help derive the contemporary regional rainfalls. Revised monthly national and regional rainfall totals for the post-1960 period (together with revised 1961-90 averages) were made available by the Met Office in 2004; these have been adopted by the NHMP. As with all regional figures based on limited raingauge networks the monthly tables and accumulations (and the return periods associated with them) should be regarded as a guide only.

The monthly rainfall figures are provided by the Met Office (National Climate Information Centre) and are Crown Copyright and may not be passed on to, or published by, any unauthorised person or organisation.
*MORECS is the generic name for the Met Office services involving the routine calculation of evaporation and soil moisture throughout Great Britain.

[^0]:    Important note:Figures in the above table may be quoted provided that their source is acknowledged. See page 12. Where appropriate, specific reference must be made to the uncertainties associated with the return period estimates. Generally, the return period estimates are based on tables provided by the Met Office" but those for Northern Ireland are based on the estimates for north-west England. The estimates relate to the specified region and span of months only (RPs may be an order of magnitude less if $n$-month periods beginning in any month are considered), they reflect rainfall variability over the period 1911-70 only, and assume a stable climate. (For further details see Tabony, R. C., 1977, The variability of long duration rainfall over Great Britain, Scientific Paper No. 37). The timespans featured do not purport to represent the critical periods for any particular water resource management zone and, normally, for hydrological or water resources assessments of drought severity, river flows and groundwater levels provide a better guide than return periods based on rainfall totals. "In some cases ranking positions of accumulated rainfalls are considered.
    All monthly rainfall totals since October 2006 are provisional.
